# Estimation of Average Years of Schooling for Japan, Korea and the United States 

February 2011

Yoshihisa Godo*

#### Abstract

This paper presents a new dataset of education stock for Japan, Korea and the US. This dataset has three major advantages over exiting ones such as Barro and Lee (2000), Kim and Lau (1995) and Nehru, Swanson and Dubey (1995). First, this paper's dataset covers nearly one hundred years while all the existing dataset do several decades in the postwar period. Second, this paper provides more detailed information such as average years of schooling by gender, age and levels of education. Third, more accuracy is guaranteed by exhaustive study on original dataset and careful treatments. The author hopes that future researchers use this paper's dataset as a "public good" to analyze the macroeconomic role of education.

[^0]
## 1. Introduction

For empirical analyses on the macroeconomic role of education, international education stock data are necessary. Among not many available datasets on education stock, many researchers use the exhaustive works by Nehru, Swanson, and Dubey (1995) , Kim and Lau (1995), and Barro and Lee (2000). In spite of their usefulness, these three datasets have limitations. One of the most serious problems is the limitation of coverage of estimation years. Their estimates are limited for a couple of decades in the postwar period. This limitation makes it difficult to analyze the economic role of education in a long-run perspective. In addition to this year coverage limitation, the accuracy of those estimates are sometimes dubious (as will be discussed in Section 6).

The purpose of this paper is to provide more accurate, detailed and longer-term dataset of education stock. This paper estimates average years of schooling for Japan, Korea and the US for nearly 100 years annually. Not only average years of schooling overall, but also average years of schooling by age groups, by levels and types of education (primary, secondary, tertiary and vocational), and by gender are estimated.

These three countries constitute an informative combination to consider the macroeconomic role of education. The US has been in the leading position in the world economy since approximately 1890. Japan is the first non-western country that ascended from the less developed stage to 'the club of wealthy nations.' Korea, which started industrialization much later than Japan, is now near to completing its economic catching-up. Many papers, both academic and non-academic, allege that the rich endowments of education in Japan and Korea constituted a key factor of their miraculous growth in the postwar period. However, because of paucity of data on education stock, this allegation has not been proved statistically. This paper's nearly-100-year estimates are suitable for analyzing the role of education in economic catchingup.

Following this section, Section 2 provides a framework of this paper’s estimation of average years of schooling. Sections 3, 4 and 5 explain details of this paper's data sources and estimation procedures for Japan, Korea and the US respectively. Section 6 presents the summary of this paper's new estimates and compares them with the existing above-mentioned three popular datasets. Section 7 states concluding remarks. This paper has four appendixes. Appendixes A, B and C prepare the data for physical capital, labor and GDP respectively. Appendix D presents the detailed tables of the new dataset.

Before this paper, the author published estimates of average years of schooling for 1888-1990 for Japan and for 1870-1990 for the US in Godo and Hayami (1999) and Godo (2001). This paper is the revised and updated version of the author's previous studies.

## 2. Methodology of estimation

### 2.1 Definition of average years of schooling

Average years of schooling can be calculated by accumulating the 'total enrollment' of corresponding years and ages after adjusting for changes in the population due to immigration and mortality. For reasons of simplicity, this paper assumes there are no differences in education level between immigrants and domestic citizens and no correlation between school carrier and mortality. Let,
$N_{w, t}=$ Total enrollment of persons aged $w$ years in year $t^{1}$; and
$G_{w, t}=$ Total number of persons aged $v$ years in year $t$.
Then, the average years of schooling in year $t$ for persons aged $x$ to $y$ years, $A S_{x-y, t}$, is defined as follows:

$$
\begin{equation*}
A S_{x-y, t}=\frac{\sum_{u=x}^{v} \sum_{w=0}^{u-1}\left(\frac{G_{u, t}}{G_{w, t+w-x}}\right) N_{w, t+w-u}}{\sum_{u=x}^{v} G_{u, u}} . \tag{1}
\end{equation*}
$$

This equation shows that in order to estimate today's education stock, we need enrollment and population data going back to many years before. For example, in order to estimate education stock for persons aged 60 years in 2000, the enrollment and population data must go back to the 1940s.

Equation (1) counts all the enrollment evenly regardless of education quality (such as qualification of teachers, student-teacher ratio and the number of schooling days per year), levels, and types. Even a repetition year is counted as one.

Barro and Lee (2000) and Nehru, Swanson and Dubey (1995) exclude repetition years from average years of schooling. This paper does not do so because over-100-year long repetition data hardly exist.

This paper does not use the national censuses’ educational attainment surveys (people's highest education level completed), either. The reason is that, since the classification of the highest level completed differs according to survey years and countries, censuses' attainment data can bring inconsistency in time-series and/or international comparison. For instance, let us consider that country A's census uses the $8^{\text {th }}$ grade as the cut-off line of primary level education and country B's census does the $6^{\text {th }}$ grade. In this case, if a person gives up schooling at the $7^{\text {th }}$ grade, country A's census counts zero years of schooling for him while country B's census counts 6 years of schooling for him.

Another assumption underlying equation (1) is that there is no depreciation in the knowledge provided in school. This may be also a strong assumption considering the fading memory from aging and the obsolescence of knowledge provided in school earlier years.

In spite of those limitations, the author believes such a basic approach expressed by equation (1) is adequate for the first attempt of constructing a long-term dataset. In future analyses, we can revise equation (1) by putting weights on enrollments according to quality, levels, and types of education. We can also consider the possibility of depreciation of knowledge by multiplying (1- $\delta)^{u-w}$ with $N_{w, t+w-u}$ in equation (1), where $\delta$ denotes the rate of depreciation. This is also a subject of the future studies .

[^1]
### 2.2 Useful transformation

There are several alternative equations that also express this paper's definition of average years of schooling. For example, let $M_{v, t}=\left(G_{v+1, t+l} / G_{v, t}\right)$ (this ratio can be defined as 'annual fluctuation rate of each cohort's total population'). Then, equation (1) can be transformed into:

$$
A S_{x-y, t}=\frac{\sum_{u=x}^{y} \sum_{w=0}^{u-1}\left(\prod_{v=1}^{u-w} M_{u-v, t-v}\right) N_{w, t+w-u}}{\sum_{u=x}^{y} G_{u, t}}
$$

The other transformation of equation (1) is given by using the enrollment ratio (defined as total enrollment divided by total number of persons). Let,
$R_{w, t}=$ Enrollment ratio for persons aged $w$ years in year $t$.
Then, equation (1) is transformed into:

$$
A S_{x-y, t}=\frac{\sum_{u=x}^{y} \sum_{w=0}^{u-1} G_{u, t} R_{w, t+w-u}}{\sum_{u=x}^{y} G_{u, t}} .
$$

While equations (1), ( 1 ') and (1") are equivalent mathematically, the data requirement for each differs. As explained in the next section, Japan's population data are available by 5 -year age groups only for pre-1920 years. For those years, equation (1') is useful because it does not need the data of 'total population by single years of age.' On the other hand, for Korea and the US, for which enrollment ratios are easier to estimate than total enrollment for early years, equation ( 1 ") is adequate.

### 2.3 Variations of average years of schooling

### 2.3.1 Average years of schooling by age groups

Many of the existing studies, such as Nehru, Swanson, and Dubey (1995) and Kim and Lau (1995), estimate education stock for the working-age population (i.e., persons aged 1564 years). This paper also treats the case of $x=15$ and $y=64$ as a baseline. Appendix D presents this paper's estimates for the younger generation (persons aged 15-39 years) and those for the elder generation (persons aged 40-64 years), too.

### 2.3.2 Average years of schooling by gender

This paper calculates equations (1), ( $1^{\prime}$ ), and ( $1^{\prime \prime}$ ) for males and females separately. Then, this paper takes the weighted average between males and females (weights are taken from
the total population by gender). This procedure produces more accurate estimates than calculating (1), (1'), and (1") for males and females inclusive. Since males usually have a higher enrollment ratio and a mortality rate than female, if we take $G, M, N$ and $R$ in those equations for both sexes inclusively, we will have an upper bias in estimates.

### 2.3.3 Average years of vocational education

The precise definition of vocational education differs according to the researcher. This paper defines the courses that provide vocational training to the graduates from the compulsory education (with no requirement of post-compulsory level education for applicants) as vocational education. This definition means that tertiary education is excluded from this paper's vocational education. Because of the limitation of data availability, this paper estimates average years of vocational education for Japan and Korea only. The concrete lists of vocational education in Japan and Korea are provided in Sections 3 and 4.

Among international organizations, there are a lot of discussions on the effectiveness of vocational education in developing countries. The World Bank emphasized vocational education in developing countries in the 1940s. The World Bank's support for vocational education, however, did not produce sufficient results. This bitter experience is known as the "fallacy of vocational school." The experiences of vocational education in Japan and Korea must be informative for today's developing countries.

### 2.3.4 Average years of schooling by levels of education

Researchers often classify education into three levels: i.e., primary, secondary and tertiary. However, classification criteria differ among researchers. This paper follows the standard format of the US's education statistics: i.e., primary education $=$ the first to eighth grades; secondary education $=$ the ninth to twelfth grades; and tertiary education = the over-twelfth grades.

## 3. Data sources for Japan

### 3.1 Population data

## 1940 and After

The national censuses provide the most popular and reliable data on the Japanese population. They have been conducted almost every fifth year since 1920; the only exception is that the 1945 census was conducted in 1947 because of the Pacific War.

The Japan Ministry of Home Affairs (MHA) cites its annual estimates of 'total population by single years of age' for inter-census years from 1948 to 2000. Many studies, such as Kim and Lau (1995), use these estimates. However, those estimates are provided for temporary use only and are unsuitable for long-term series analyses. For example, the Bureau did not revise the estimates for 1966-69 even after
the results of the 1970 census became available. As a result, the Bureau estimates for 1966-69, which were updated from the 1965 census, do not connect to the 1970 census. Thus, for the inter-census years for 1947-2000, this paper takes log-linear interpolations between the censuses' population data with log-linear curves instead of using the MHA's estimates ${ }^{2}$. Since erratic movements in population are expected during a wartime period, this paper does not attempt to estimate for1941-46.

1920-1939
For these years, Japan Bureau of Statistics (1970) provides its annual estimates of population by age, which are consistent with the 1920, 1930 and 1940 censuses. This paper use the Bureau's estimates with no adjustment.

## Prior to 1920

Although no censuses were conducted before 1920, two well-known data sources for these years have been prepared by researchers. One is Japan Ministry of Education (1969), in which the population by single schooling age is estimated for every fifth year from 1870 onward. Since Japan Ministry of Education (1969) data is limited to cohorts who were born after 1840, however, this paper does not use it to determine 'population by age' or 'annual fluctuation rate of each cohort's total population.' Instead, Japan Ministry of Education (1969) serves another purpose in the next subsection.

Umemura et al. (1988) is the other well-known data source for agedistribution of the total population on which this paper relies. This source estimates total population by 5-year groups (namely, aged under 5, aged 5-9, aged 10-14 and so forth) for every year beginning in 1871 . Thus, average years of schooling can be estimated by equation ( $1^{\prime}$ ).

A major problem here is that the top population group in Umemura et al. (1988) is 'age 60 years and over.' So in order to get the working-age population (persons aged $15-64$ years), the total number of persons aged $60-64$ years must be estimated in advance. First, this paper assumes that persons aged over-59 years decreases $\alpha$ times faster than those aged 55-59 years and that the value of $\alpha$ remains constant for 5 years. Then, this paper can calculate the value of $\alpha$ for 1915-20 by the following equation (as mentioned above, 1920 is the first year when the national census was conducted and, hence, the total number of persons aged 60-64 years is available).

$$
\begin{equation*}
\alpha=\frac{\frac{G_{S, 1920}-G_{60-64,1920}}{G_{S, 1915}}}{\frac{G_{60-64,1920}}{G_{55-59,1915}}} \tag{2}
\end{equation*}
$$

where,

[^2]\[

$$
\begin{aligned}
& G_{u-w, t}=\text { Total number of persons aged } u-w \text { years in year } t ; \\
& G_{s, t}=\text { Total number of persons aged over-59 years in year } t .
\end{aligned}
$$
\]

Applying this $\alpha$ to all the pre-1920 years, the following equation is derived.

$$
\begin{equation*}
\frac{G_{60-64, t}}{G_{55-59, t-5}}=\frac{G_{S, t}-G_{60-64, t}}{\alpha G_{S, t-5}} . \tag{3}
\end{equation*}
$$

Solving equation (3) for $G_{60-64, \text { t }}$, this paper obtains the equation below that is applicable to estimation of the number of persons aged 60-64 years.

$$
\begin{equation*}
G_{60-64, t}=\frac{G_{S, t} G_{55-59, t-5}}{G_{55-59, t-5}+\alpha G_{S, t-5}} . \tag{4}
\end{equation*}
$$

The next step is estimating 'annual fluctuation rate of each cohort's total population.' Since accessible population data are given only by 5 -year age groups, additional assumptions are inevitable for estimating 'annual fluctuation rate of each cohort's total population.' Assuming that 'annual fluctuation rate of each cohort's total population' is constant in a 5 -year age group, this paper takes rough approximation by the following equations (5) and (6) (note that the total population by 5 -year age groups, instead of that by single years of age, is required in these equations).
(5) $M_{5 I+j, t} \approx\left(\frac{\sum_{k=5}^{9} G_{5 I+k, l+5}}{\sum_{k=0}^{4} G_{5 I+k, t}}\right)^{\frac{1}{5}} \quad($ for $\quad I=1, \ldots, 11 \quad$ and $\quad j=0, \ldots, 4)$
(6) $M_{5 I+j, t} \approx \alpha\left(\frac{\sum_{k=5}^{9} G_{5 I+k, t+5}}{\sum_{k=0}^{4} G_{5 I+k, t}}\right)^{\frac{1}{5}} \quad($ for $\quad j=1, \ldots, 3)$

Applying Umemura et al.'s population data to equations (5) and (6), this paper obtains $M_{v, t}(\mathrm{v}=6, \ldots, 63)$ for all the years after 1871. Unfortunately, however, there is not reliable annual population data for the years before 1871. This paper assumes that
$M_{v, t}(\mathrm{v}<64, \mathrm{t}<1871)$ is equivalent to $M_{v, 1871} .^{3}$

### 3.2 Enrollment data

1946-2000
Both the Japanese education system and statistics were extensively revised in 1946 under the Occupation, which have basically remained the same since. In contrast to the prewar period, the education system is now simplified and wellorganized. In addition, educational statistics are now based on systematic and userfriendly formulas. As a result, this paper finds the total enrollment by grade for every school type (except special schools and university graduate courses; only the total enrollment is available) in the Fundamental School Survey, a popular annual report put out by the Japanese Ministry of Education. Assuming again that people enter primary school at age 6 and continue on to upper grades without repeating, this paper replaces 'total enrollment by grade’ with 'total enrollment by single years of age.' As for special schools, this paper assumes that their percentage distribution of enrollment among grades is the same as that of ordinary schools. As for university graduate courses, this paper divides the total enrollment into the enrollment of age 22 years and that of age 23 years in proportion to the total populations of the two age groups. In this way, the total enrollment by single years of age is determined ${ }^{4}$.

## 1873-1945

The Japanese education system from 1873 to 1945 was complicated, rendering it difficult to describe in straightforward terms. Although the system was revised frequently over the period, its complexity remained because its revisions were often quick fixes as opposed to long-term repairs. In addition, curricula in those days were sometimes stipulated so vaguely that students of different ages and various academic backgrounds studied in the same class.

Another obstacle for this study was the complexity of the educational statistics published during the period. While the Japan Ministry of Education conducted various kinds of school surveys and published the major results in annual reports, the survey items and report formulas varied by volume, and technical terms were often used without clear definitions, making them too complicated to use for

[^3]research purposes.
But after the Pacific War, the Ministry re-organized the prewar annual reports into special volumes and published them for research use. Although some vagueness and inconsistencies still remain in those volumes, they provide us with sufficient information. One volume in particular, Japan Ministry of Education (1957), has proven to be the best data source for our study in that it provides data on enrollment by type of school and type of course.

The major problem in using Japan Ministry of Education (1957) is that students' age distribution is not reported there. This paper solves this problem with the following two steps. First, by basing a conjecture on the literature of prewar Japan's education system, this paper assumes a 'model' pattern of the starting and ending ages for each course and for each year. Second, this paper distributes the total enrollment of each course into the relevant age cohorts in proportion to the cohorts' total populations.

In order to implement this two-step solution, this paper again needs the data of 'total population by single years of age.' As discussed in Section 3.1, Japan Bureau of Statistics (1970) provides such data for 1920 and thereafter ${ }^{5}$. For the years before 1920, Japan Ministry of Education (1969) presents useful information (note that, unlike the discussion in Section 3.1, this paper's concern is restricted to school ages in this case). Japan Ministry of Education (1969) estimates the population of all school ages as of January 1 every fifth year from 1870 to 1920 . For the other years before 1920, this paper takes log-linear interpolations to get the total population by single years of age.

One consideration here is the difference between the calendar year and the Japanese school year. The Japanese school year, which is used in most of the Ministry of Education statistics, begins April 1 and ends March 31; for example, the population data for January 1, 1910, corresponds to the enrollment data for 1909. On the other hand, the population censuses and Japan Bureau of Statistics (1970) are surveyed on or estimated for October 1 of each year and thus correspond to that year's enrollment data.

The following shows the 'model' patterns that this paper assumes for Japan Ministry of Education (1957).

## 1) Shogakko (Primary School)

1873-80: Jido Sosu (total enrollment of primary school) is counted as students aged 6-13 years.

1881-85: Jinjo-ka Jido $S u$ (total enrollment of ordinary primary school) is counted as students aged 6-11 years. 'Koto-ka Jido Su (total enrollment of higher primary school)' is counted as students aged 12-13 years.

1886-90: Jinjo-ka Jido $S u$ (total enrollment of ordinary primary school) is counted as students aged 6-9 years old. Jinjo-Hoshu-ka Jido Su (total enrollment of supplementary course of ordinary primary school) is counted as students aged 6-8

[^4]years ${ }^{6}$. Koto-ka Jido $S u$ (total enrollment of higher primary school) is counted as students aged 10-13 years.

1891-97: Jinjo-ka Jido Su (total enrollment of ordinary primary school) is counted as students aged 6-9 years. Jinjo-Hoshu-ka Jido Su (total enrollment of supplementary course of ordinary primary school) is counted as students aged 10-11 years. Koto-ka Jido Su (total enrollment of higher primary school) is counted as students aged 10-13 years. Koto-Hoshu-ka Jido Su (total enrollment of supplementary course of higher primary school) is counted as students aged 14-15 years.

1898-: Jinjo-ka Jido Su (total enrollment of ordinary primary school) is counted as students aged 6-11 years. Jinjo-Hoshu-ka Jido Su (total enrollment of supplementary course of ordinary primary school) is counted as students aged 12-13 years. Koto-ka Jido Su (total enrollment of higher primary school) is counted as students aged 12-13 years old. Koto-Hoshu-ka Jido Su (total enrollment of supplementary course of higher primary school) is counted as students aged 14-15 years.

## 2) Chugakko (Ordinary Middle School)

1873-80: Seito Sosu (total enrollment of ordinary middle school) is counted as students aged 14-19 years.

1881-85: Seito Sosu (total enrollment of ordinary middle school) is counted as students aged 12-17 years.

1886-1942: Seito Sosu (total enrollment of ordinary middle school) is counted as students aged 12-16 years.

1943-: Seito Sosu (total enrollment of ordinary middle school) is counted as students aged 12-15 years.

## 3) Koto-Jogakko (Girls’ High School)

1895-98: Honka Seito Sosu (total enrollment of ordinary course of girls’ high school) is counted as students aged 10-15 years. 'Gigei-Senshu-ka oyobi Jikka Seito Sosu (total enrollment of handcraft and vocational courses of girls’ high school)’ is counted as students aged 14-15 years.

1899-: Honka Seito Sosu (total enrollment of ordinary course of girls’ high school) is counted as students aged 12-15 years. Gigei-Senshu-ka oyobi Jikka Seito Sosu (total enrollment of handcraft and vocational courses of girls’ high school) is counted as students aged 14-15 years.
4) Jitsugyo-Gakko (Vocational Middle School) and Totei-Gakko (Apprentices’ School)

[^5]1894-98: Totei-Gakko Seito Sosu (total enrollment of apprentices' school) is counted as students aged 12-14 years.

1899-1904: Jitsugyo-Gakko Seito Sosu (total enrollment of vocational middle school) is counted as students aged 14-16 years. Totei-Gakko Seito Sosu (total enrollment of apprentices' school) is counted as students aged 12-14 years.

1905-1942: Koshu-Jitsugyo-Gakko Seito Sosu (total enrollment of vocational middle school type A) is counted as students aged 14-16 years. 'Otsushu-Jitsugyo-Gakko Seito Sosu (total enrollment of vocational middle school type B)’ and 'Totei-Gakko Seito Sosu (total enrollment of apprentices’ school)' are counted as students aged 1214 years.

1943 -: 'Jitsugyo-Gakko Seito Sosu (total enrollment of vocational middle school)' is counted as students aged 14-15 years.
5) Jitsugyo-Hoshu-Gakko (Vocational Supplementary School), Seinen-Kunrensho (Young Men's Training Institute), and Seinen-Gakko (Young Men's Training School)
1886-1907: Jitsugyo-Hoshu-Gakko Seito Sosu (total enrollment of vocational supplementary school) is counted as students aged 10-12 years.

1908-1934: Jitsugyo-Hoshu-Gakko Seito Sosu (total enrollment of vocational supplementary school) is counted as students aged 12-14 years. Seinen-Kunrensho Seito Sosu (total enrollment of young men's training institute), where an allegedly considerable portion of students are double-schooling at Jitsugyo Hoshu Gakko, is multiplied by 0.6 and then counted as students aged 16-19 years. ${ }^{\text {. }}$

1935-: Seinen-Gakko Futsu-ka Seito Sosu (total enrollment of ordinary course of young men's training school) is counted as students aged 12-13 years. Seinen-Gakko Hon-ka Danshi Seito Sosu (total enrollment of boys' regular course of young men's training school) is counted as students aged 14-18 years. Seinen-Gakko Hon-ka Joshi Seito Sosu (total enrollment of girls' regular course of young men's training school) is counted as students aged 14-16 years. Seinen-Gakko Kenkyuka Danshi Seito Sosu (total enrollment of boys' graduate course of young men’s training school) is counted as students aged 14-18 years. Seinen-Gakko Kenkyu-ka Joshi Seito Sosu (total enrollment of girls' graduate course of young men's training school) is counted as students aged 17 years.

## 6) Koto-Gakko (High School)

1886-1918: Hojuka Seito Sosu (total enrollment of pre-preparatory course of high school) is counted as students aged 12-13 years. Yoka Seito Sosu (total enrollment of

[^6]preparatory course of high school) is counted as students aged 14-16 years. Honka Seito Sosu (total enrollment of regular course of high school), Yaku-Gakka Seito Sosu (total enrollment of pharmaceutical department of high school), and Kogakubu Seito Sosu (total enrollment of technological department of high school) are counted as students aged 17-19 years. Igakka Seito Sosu (total enrollment of medical department of high school) and Hogakubu Seito Sosu (total enrollment of law department of high school) are counted as students aged 17-20 years.

1919-42: Jinjoka Seito Sosu (total enrollment of ordinary course of high school) is counted as students aged 12-15 years. Kotoka Seito Sosu (total enrollment of higher course of high school)' is counted as students aged 16-18 years.

1943-: Jinjoka Seito Sosu (total enrollment of ordinary course of high school) is counted as students aged 12-15 years. Kotoka Seito Sosu (total enrollment of higher course of high school) is counted as students aged 16-17 years.

## 7) Senmon-Gakko (College), Jitsugyo-Senmon-Gakko (Vocational College)

1905-42: Senmon-Gakko Seito Sosu (total enrollment of college) and Jitsugyo-Senmon-Gakko Seito Sosu (total enrollment of vocational college) are counted as students persons aged 17-19 years.

1943-: Senmon-Gakko Seito Sosu (total enrollment of college) and Jitsugyo-SenmonGakko Seito Sosu (total enrollment of vocational college) are counted as students aged 16-18 years.

## 8) Shihan-Gakko (Normal School)

1886-1906: Danshi Seito Sosu (total enrollment of boys' course of normal school)' is counted as students aged 17-20 years. 'Joshi Seito Sosu (total enrollment of girls’ course of normal school)' is counted as students aged 15-17 years.

1907-24: Dai-ichibu Seito Sosu (total enrollment of normal school Type I)' is counted as students aged 15-18 years. 'Dai-nibu Seito Sosu (total enrollment of normal school Type II)’ is counted as students aged 17 years.

1925-30: Dai-ichibu Seito Sosu (total enrollment of normal school Type I)' is counted as students aged 14-18 years. 'Dai-nibu Seito Sosu (total enrollment of normal school Type II)' is counted as students aged 17 years.

1931-42: Dai-ichibu Seito Sosu (total enrollment of normal school Type I) is counted as students paged 14-18 years. Dai-nibu Seito Sosu (total enrollment of normal school Type II) is counted as students aged 17-18 years.

1943 -: Honka Seito Sosu (total enrollment of regular course of normal school) is counted as students aged 16-18 years. Yoka Seito Sosu (total enrollment of preparatory course of normal school) is counted as students aged 14-15 years.
9) Koto-Shihan-Gakko (Higher Normal School)

1886-94: Seito Sosu (total enrollment of higher normal school) is counted as students aged 21-23 years.

1895-98: Danshi Seito Sosu (total enrollment of boys' higher normal school) is counted as students aged 17-23 years. Joshi Seito Sosu (total enrollment of girls’ higher normal school) is counted as students aged 17-20 years.

1899-1908: Seito Sosu (total enrollment of higher normal school) is counted as students aged 17-20 years.

1909-1942: Danshi Seito Sosu (total enrollment of boys' higher normal school) is counted as students aged 17-20 years. 'Joshi Seito Sosu (total enrollment of girls’ higher normal school)' is counted as students aged 16-19 years.

1943 -: Seito Sosu (total enrollment of higher normal school) is counted as students aged 16-19 years.
10) Daigaku (University)

1886-1906: Gakubu Gakusei Sosu (total enrollment of undergraduate course of university) is counted as students aged 20-22 years. Daigakuin Gakusei Sosu (total enrollment of graduate course of university) is counted as students aged 23-24 years.

1907-18: Gakubu Gakusei Sosu (total enrollment of undergraduate course of university) is counted as students aged 20-22 years. Daigakuin Gakusei Sosu (total enrollment of graduate course of university) is counted as students aged 23-24 years. Yoka Gakusei Sosu (total enrollment of preparatory course of university) is counted as students aged 17-19 years.

1919-42: Gakubu Gakusei Sosu (total enrollment of undergraduate course of university) is counted as students aged 19-21 years. Daigakuin Gakusei Sosu (total enrollment of graduate course of university) is counted as students aged 22-23 years. Yoka Gakusei Sosu (total enrollment of preparatory course of university) is counted as students aged 16-18 years.

1943-: Gakubu Gakusei Sosu (total enrollment of undergraduate course of university) is counted as students aged 18-20 years. Daigakuin Gakusei Sosu (total enrollment of graduate course of university) is counted as students aged 21-22 years.

## 11) Moa Gakko (School for Handicapped Children)

1923-42: Shotobu Seito Sosu (total enrollment of primary school for handicapped children) is counted as students aged 6-11 years. Chutobu Seito Sosu (total enrollment of secondary school for handicapped children) is counted as students aged 12-16 years.

1943-: Shotobu Seito Sosu (total enrollment of primary school for handicapped children) is counted as students aged 6-11 years. Chutobu Seito Sosu (total enrollment of secondary school for handicapped children) is counted as students aged

12-15 years.

## 1830-72

Estimating the total enrollment for the years before 1873 is the most challenging part of this paper's process. In fact, because there was no modern education system before 1873, most long-term educational statistics do not cover these years. The author hopes this paper provides a new perspective on Japanese premodern educational history.

Before 1873, when the first modern system was introduced in Japan, children learned their 3R's at private schools, called Terakoya, where educated classes such as samurai, doctors and Buddhist priests taught pupils according to their own techniques. Terakoya schools spread all over the nation. However, because of the limitation of literature and statistics, specific details, such as curricula, schooling years, and the total number of schools and pupils, are not well-known.

One of the most prominent works on Terakoya school is Umihara (1988), on which our estimates heavily rely. In Umihara's view, an average Terakoya school course took eight years, from ages 6 to 13 years, and the curriculum was so scant that eight years of schooling at a Terakoya school is almost equivalent to four years at a modern elementary school.

Another important data source on Terakoya school is Nihon-KyoikushiShiryo (Statistics of Japanese Educational History), published by the Ministry of Education in an unnamed year (presumably around 1889). In it, the local governments in Japan fulfill the Ministry of Education's request (presumably made around 1879) to review the history of Terakoya schools in their jurisdictions. They listed as many Terakoya schools as possible by consulting literature and old citizens and villagers. The details of each Terakoya school, like the name of the school, the status of the instructor, opening and closing years, average number of pupils, and main curriculum, were also reported, albeit unsystematically. Although the survey was far from exhaustive, as many as 15,600 Terakoya schools were noted in Nihon-Kyoikushi-Shiryo. This paper uses Nihon-Kyoikushi-Shiryo extensively but also cautiously.

Using these two reports (i.e., Umihara(1988) and Nihon-Kyoikushi-Shiryo), this paper estimates in three steps the total enrollment (sum of all the grades) in Terakoya school for every year from 1818 to 1872. First, this paper sets 1868 as a benchmark year and, based on Umihara's results, estimates its total enrollment number. Second, this paper sets ten sub-benchmark years and, based on Nihon-Kyoikushi-Shiryo and the result of the first step, this paper estimates the total enrollment for those years. Finally, this paper takes interpolations for the non-subbenchmark years.

Unfortunately, we do not have enough information about the age distribution of the total enrollment in Terakoya schools. This paper simply assumes that the total enrollment was distributed uniformly across presumable Terakoya-schooling ages (from ages 6 to 13 years).

To estimate average years of schooling, adjustments for the difference in quality of schooling between Terakoya and modern schools are necessary. Based on Umihara's view mentioned above, it may be reasonable to assume that attending a Terakoya school for one year is equivalent to attending a modern school for half a
year. Therefore, instead of using the estimates of the total enrollment in Terakoya school as they are, this paper multiplies them by 0.5 .

## (i) The total enrollment in 1868 (benchmark year)

This paper estimates the total enrollment in 1868 by multiplying school attendance rate and school-age population based on Umihara's study.

According to Umihara, the national average of the Terakoya school attendance rate (measured by 'total enrollment in Terakoya school' divided by 'total number of persons aged 6-13 years') in 1868 is $24.5 \%$ for male and $5.8 \%$ for female. Although the study contains some controversial points, many researchers basically accept it.

Umihara estimates the 'total number of persons aged 6-13 years (i.e. presumable Terakoya-schooling ages)' claims 14.6 percent in 1873. Unfortunately, there is no reliable population data for 1868. Therefore, assuming that there is no significant change in population for several years after 1868, this paper uses the data of the total population for 1871 ( $17,211,271$ males and $17,058,200$ females), the first year Umemura et al. (1988) provide population data from. Based on the population data and Umihara's argument, this paper estimates the total enrollment in Terakoya school in 1868 to be 760,096 with the following equation (7):
(7) $17,211,271 \times 0.146 \times 0.245+17,058,200 \times 0.146 \times 0.058=760,096$.

## (ii) The total enrollments in sub-benchmark years

For most of the Terakoya schools in Nihon-Kyoikushi-Shiryo, the opening and closing years are reported under the 'dynastic calendar,' the traditional Japanese calendar. Under the dynastic calendar, an emperor arbitrarily announces the beginning and the name of a new dynastic era. Every year is given a name by combining the name of the dynastic era and the number of years into the era; for example, 1846 is called 'Koka year 3' since 'Koka' started in 1844 when Emperor Ninko declared the beginning of a new dynastic era.

The dynastic calendar structure is related to some doubts about the accuracy of the opening and closing years of Terakoya schools cited in Nihon-KyoikushiShiryo. Specifically, as Ishikawa (1929) notes, an unbelievably large portion of Terakoya schools in Nihon-Kyoikushi-Shiryo opened in the first years of dynastic eras. Although we are uncertain of the actual events, Ishikawa's finding implies the possibility that many of Terakoya school managers falsely claimed to have opened their schools in the first dynastic years for the purpose of elevating their schools' history since the 'first years' were believed to be lucky.

Taking Ishikawa's argument into consideration, this paper uses only the name of the dynastic era for the opening and closing years; in other words, the exact numbers of the year of the dynastic eras are omitted. In this way, a distribution table of the opening and closing era of Terakoya schools appearing in Nihon-KyoikushiShiryo (Table 1) is compiled.

Based on Table1, this paper finds the number of the Terakoya schools that existed in the first year of each dynastic era, which this paper refers to as subbenchmark years from now on (Table 2). For example, the total number of Terakoya schools open in 'Koka year 1 ' is determined by summing up the number of Terakoya schools that opened before the Koka era and closed in or after the Koka era.
[Table 2]

In Nihon-Kyoikushi-Shiryo, the enrollment of each Terakoya school is also surveyed albeit unsystematically. According to Ishikawa's study, the average enrollment of Terakoya school was on a downward trend in the 19th century (Table $3)$.
[Table 3]
By multiplying the total number of schools in Table 2 and average enrollment in Table 3, the total enrollment for Terakoya schools (Table 4) is found. Comparing the total enrollment in 1868 in Table 4 (i.e. 137,248) with this paper's estimate previously mentioned (i.e., 760,096), it is determined that Nihon-KyoikushiShiryo covers 18.1 percent of all the Terakoya schools in Japan. Assuming that the coverage rate of Nihon-Kyoikushi-Shiryo is constant for all sub-benchmark years, this paper thus finds the total enrollment in Japan for all those years (Table 5). ${ }^{8}$
[Tables 4 and 5]
Finally, the total enrollment in Japan for the whole period from 1830 to 1872 is found by interpolation between the benchmark and sub-benchmark years (Table 5).

### 3.2.3 Average years of schooling by gender

Most of the data mentioned in Sections 3.2.1 and 3.2.2 are available by gender. The exception is enrollment before 1872. Since there is only little information available about the movement of the gender gap for these years, this paper simply assumes that the male/female ratio is the same as that of Umihara's estimate for Terakoya schools as of the early Meiji period.

### 3.2.4 Average Schooling of Vocational Education

This paper assumes the following courses as vocational education. Most of

[^7]these courses belong to the secondary educational level: ${ }^{9}$

```
Jikka Koto-Jogakko (vocational course of girls' high school)
Shogakko Jinjo-Hoshu-ka (supplementary course of ordinary primary school)
Shogakko Koto-Hoshu-ka (supplementary course of higher primary school)
Jitsugyo Gakko (vocational middle school)
Koshu-Jitsugyo Gakko (vocational middle school, type A)
Otsushu-Jitsugyo Gakko (vocational middle school, type B)
Jitsugyo Hoshu Gakko (vocational supplementary school)
Totei Gakko (apprentices’ school)
Seinen Kunrensho (young men’s training institute)
Seinen Gakko (young men's training school)
Koto Gakko Shokugyoka (vocational course of senior high school)
Koto Senmon Gakko (technical college)
```

## 4. Data Sources for Korea

### 4.1 Population Data

1955-2000
The national censuses provide the most popular and reliable data on the Korean population. They have been conducted almost every 5th year since 1955; the only exception is 1966 instead of 1965. For the census years, this paper uses these census data without adjustment.

For inter-census years, this paper takes log-linear interpolations for each cohort.

## 1943-54

For reasons of data reliability, this paper does not attempt to estimate average schooling for these years.

## Prior to 1943

The 1930 and 1935 population censuses provide the total population by age. ${ }^{10}$ For 1931-34, this paper takes log-linear interpolations by cohort. For 1935-42 and pre-1930 years, this paper takes extrapolations based on Ishi's (1972) mortality rates.

### 4.2. Enrollment data

[^8]Korean education system in this period is characterized by 6-3-3 system. 6-year elementary school and 3-year middle school are compulsory. After that, students can go to 3-year general or vocational high school. High school graduates can enter junior colleges or universities. The graduate courses of universities are the highest level of education. The handicapped attend special schools that consist of elementary, middle and high classes.

Besides these regular schools, there are several schools that provide more flexible and practical education under the supervision of the Korean Ministry of Education: namely, civic school, civic high school, trade high school, miscellaneous school, miscellaneous high school, miscellaneous undergraduate course, miscellaneous junior college, and industrial college. This paper assumes that civic school and miscellaneous school provide middle school-level education; civic high school, trade high school and miscellaneous high school do high school-level education; miscellaneous undergraduate course, miscellaneous junior college, and industrial college do post-secondary-level education.

The data source is the Statistical Yearbook of Education published annually from the Korean Ministry of Education. This series of yearbooks contains data of enrollment by age, by gender, by types of school and mostly by grade. In some cases, the enrollment is given not by single years of age but by plural-year age groups. In such cases, this paper assumes the uniform distribution of enrollment among the ages. If an age group is given as either 'age $x$ years and over' or 'age $x$ years and lower,' this paper counts such enrollment as students aged $x$ years. This paper does not count the enrollment of age 40 years and over, which takes insignificant figures. For special schools, for which enrollment by grade is not reported, this paper assumes the distribution of enrollment by grade in special school is same as that of ordinary school.

Another problematic part is how to estimate the number of Korean students studying abroad. The Korea Research Foundation (KRF) collects the annual data of number of PhDs obtained by Koreans from foreign universities for the postwar period. But, because the KRF's data are based on self-reports, they are not exhaustive. In addition, students who studied abroad without getting PhDs are not included in the KRF's survey.

In spite of these limitations, the KRF is the only data source on which this paper can rely. Assuming that it needs 5 years on average to obtain a PhD and there are three times as many students studying abroad as in the KRF's list, this paper uses the following equation;

$$
\begin{equation*}
F_{t}=4 \times \sum_{i=t+1}^{t+5} D_{i} \tag{8}
\end{equation*}
$$

where,
$F_{t}=$ Number of Korean students studying abroad in year $t$; and
$D_{t}=$ The KRF's data of the number of PhDs obtained by Korean students from foreign universities in year $t$.
The age and gender structures of students studying abroad are assumed to be the same as those of graduate course students in domestic universities and colleges.

This paper counts civic high school, trade high school, miscellaneous high school, and vocational high school as vocational education.

## 1945-65

Official school statistics are unavailable for these years. Fortunately, however, McGinn et al (1980) provide their own estimates of enrollment for these years. McGinn et al estimate the
total enrollment for five types of education: primary, middle, academic secondary, vocational secondary, and colleges \& universities. This paper estimates enrollment ratios of these five types of education from the following equation;

$$
\begin{equation*}
R_{z, w, t}=\frac{R_{z, w, 1966} T E_{t} T P_{z, 1966}}{T E_{1966} T P_{z, t}} \quad(t=1945, \ldots, 65) \tag{9}
\end{equation*}
$$

where,
$R_{z, w, t}=$ Total enrollment ratio of type $z$ school for persons aged $w$ years in year $t$. ( $z=$ primary, middle, academic secondary, vocational secondary, and colleges \& universities)
$T E_{z, t}=$ Total enrollment of type $z$ school in year $t$ (from McGinn et al., 1980), and
$T P_{t}=$ Total population in year $t$ (from Maddison, 1994).
This process simultaneously provides enrollment ratio by levels of education. Summation of these five enrollment ratios gives the total enrollment ratio.

1943, 44

For 1943 and 1944, this paper takes linear interpolations between enrollment ratios of 1942 and 1945 (enrollment ratio of 1942 will be obtained in the next part of this section).

1912-42

Korea was under Japan’s colonization from 1910 to 1945. The Governor-General of Chosen, Japan's colonial headquarters in Korea, introduced a modern education system in 1911. School Statistics of Chosen, annual reports published by the Governor-General of Chosen, provide the enrollment data by types of school for 1912-42. For most school types, enrollment is reported by gender, grade and race (Korean, Japanese and others), too. Assuming that people continue on to upper grades without repeating, 'total enrollment by grade' can be translated into 'total enrollment by age.'

School Statistics of Chosen are not user-friendly statistics while they contain surprisingly minute information on school enrollment. For example, the survey items and report formulas of School Statistics of Chosen vary by volume, and technical terms are often used without clear definitions. Therefore, after consulting with the literature on prewar Korea's education system, this paper makes the best efforts in organizing the data of School Statistics of Chosen.

The following is the details of this paper's data treatments on School Statistics of Chosen:

Koritsu Shogakko Dai-nibu (Type-II Course of Public Primary School) Shiritsu Futsu Gakko (Private Ordinary School) and Dochiji Nintei Gakko (Schools authorized by the governors)

These schools offered the most basic part of formal primary education for Korean children. They had two types courses: ordinary courses and higher ordinary courses. The ordinary courses were the lowest stage of education, and graduates from the ordinary courses were allowed to go on to the higher ordinary courses.

Officially, the schooling year of ordinary courses was 4 (ages 8-11 years) before 1922 and 6 (ages $6-11$ years) thereafter. In practice, however, it needed considerable years to completely replace the older system. To make the matter more complicated, some schools had already started 6-year ordinary courses in 1921 (O, 1979, p.276). These factors imply that simple transformation from 'enrollment by grade' to 'enrollment by age' are inadequate for 1921 and the following several years. So, this paper does not use the data on 'enrollment by grade' for 192126. Instead, the data of 'total enrollments' (all grades inclusive) are used, and divided into ages 6-11 years assuming that the age structure of elementary school students for these years is same as that for 1927.

2-year higher ordinary courses , whose enrollments are reported for 1922 and thereafter, were counted as grades 7 and 8 . The supplementary courses for ordinary and higher ordinary courses were counted as grades 7 and 9 respectively. This paper regards these supplementary courses as vocational education.

## Kanritsu Shogakko (State-run Primary School) and Koritsu Shogakko Dai-ichibu (Type-I Course of Public Primary School)

These schools were founded mainly for Japanese children in Korea while they accepted Korean children of the privileged classes. The schooling years, courses and curricula of those schools are the same as those in elementary school in Japan. Those schools had 6-year ordinary primary schooling (grades 1 to 6 ) and 4 -year higher primary schooling (grades 7 to10) even before 1922. Those schools had supplementary courses, too. This paper counts the enrollment of supplementary courses of ordinary primary schooling as students of grade 7. The enrollment of supplementary courses of higher primary schooling is counted as students of grade 11.

Chugakko (Middle School), Koritsu Kokumin Gakko Fusetsu Kan-i Gakko (Simplified School attached to Public Primary School), Jitsugyo Gakko (Vocational School), Jitsugyo Hoshu Gakko (Vocational Supplementary School), Shihan Gakko (Normal School), Koto Jogakko (Girls’ High School)

These schools accept graduates of the above mentioned primary schools. The enrollment of the first year of these schools is counted as students of grade 7. This paper regards Jitsugyo Gakko and Jitsugyo Hoshu Gakko as vocational education.

## Senmon Gakko (Vocational College), Yoka (Preparation School), Daigaku (University), Daigakuin (Graduate Course of University)

Only graduates from Chgakko could proceed to these upper schools. This paper assumes that the students enter Senmon Gakko ${ }^{11}$, Yoka, Kanritsu Daigaku, Daigakuin (including Sen-ka, Choko-ka, and Senko-ka) at ages 17, 16, 18, and 22 years respectively. Senka, Chokoka, and Senmonka in Kanritsu Daigaku are counted as students aged 22 years.

## Sodang, Kakushu Gakko (Miscellaneous School)

Informal schools, called Sodang and Kakushu Gakko, also provided popular education

[^9]in prewar Korea. The total enrollments of Sodang and miscellaneous school are taken from Chosen Statistical Yearbook published by the Governor-General of Chosen. ${ }^{12}$ This paper assumes that the education level of Sodang equaled that of ordinary courses of primary school and that of Kakushu Gakko is equal to elementary and middle (for female, girls' high) schools. Assuming that age structure of enrollment of those schools was the same as that of elementary school, middle school, and girl's high school, this paper estimates enrollment by age for Sodang and Kakushu Gakk,.

## Korean students outside the Korean Peninsula

Korean students outside the Korean Peninsula should not be ignored. Because the Governor-General of Chosen restrained the opportunities of secondary and tertiary education for Koreans, it was not rare that Korean families sent their children to mainland Japan, China and other foreign countries to seek chances of secondary and tertiary education. There are no official statistics about those Korean students outside the Korean Peninsula. Fortunately, however, Dong-a Ilbo, a Korean newspaper occasionally reported its estimates on this data. ${ }^{13}$ According to Dong-a Ilbo, the total enrollment of Korean students outside the Korean Peninsula was 3,793 for 1917, 4,800 for 1920, and 9,066 for 1924. Among them, the enrollment by gender is available only for 1917. This paper assumes that the female/male ratio was constant throughout the prewar period. The total enrollment of Korean students outside the Korean Peninsula for 1912-16, 191819, 1921-23, and 1925-45, are estimated by log-linear interpolations and extrapolations. This paper assumes that $60 \%$ of Korean students outside the Korean Peninsula were enrolled in the secondary-level schools and the remaining $40 \%$ were enrolled in the tertiary-level schools ${ }^{14}$. This paper assumes that age-structure of Korean students outside of the Korean Peninsula is the same as that of the inside peninsula.

## Prior to 1912

In official school statistics, sufficient enrollment data is limited to only 1912 and thereafter. In order to cope with this problem, this paper uses the data of illiteracy rates surveyed in the 1930 population census. The census reports the illiteracy rate by gender and by four age groups; ages 20-24 years, ages 30-39 years, ages 40-59 years, and age 60 years and over (Table $6)$.

## [Table 6]

Fortunately, for persons aged 20 to 24 years as of 1930, sufficient data are available to

[^10]apply equation (1) (as described above). Namely, $A S_{20-24,1930}$ is calculated as 1.783 for males and 0.118 for females. Referring to their illiteracy rates (i.e., 0.443 for males and 0.858 for females), this paper estimates $A S$ for the other age groups from illiteracy rate (denoted as $I L$ ) according to the following equation;
\[

$$
\begin{equation*}
\ln (A S)=\frac{I L-0.443}{0.858-0.443} \ln (0.118)+\frac{0.858-I L}{0.858-0.443} \ln (1.783) . \tag{10}
\end{equation*}
$$

\]

The results are also shown in Table 6. ${ }^{15}$ This paper assumes that all the enrollment for pre-1912 years was the primary level of education.

## 5. Data sources for the United States

## 5. 1 Population data

1900-2000
One of the most popular data sources for the age structure of the total population in the United States is the results of the national population censuses that take place every 10 years. Beginning at the 1880 census, 'total population by single years of age' is surveyed in every census year. However, it is well known that census data overestimate the number of people whose age is a multiple of 5; this misrepresentation is allegedly owed to the respondents' tendency to prefer clear-cut numbers. In this sense, the national census data are not accurate enough as the data source of 'total population by single years of age.'

In order to resolve this 'every-5-year' problem, the US Bureau of the Census has publicized its special estimates of 'total population by single years of age' by using various vital and migrant data as well as census data. In particular, from four volumes of the US Bureau of the Census (1965, 1974, 1982, 1993, 2001), we get the Bureau's special estimates of 'population by single years of age' for all the years from 1900 to 2000.

The use of the US Bureau of the Census volumes (1965, 1974, 1982, 1993, 2001) requires clarification of two points. First, the Bureau's treatment of military personnel overseas is inconsistent; more precisely, the Bureau's figures of the total population include the number of military personnel overseas for 1940-59 but not for other years. Hence, military personnel overseas from the total population must be subtracted for those twenty years. Yet, while the total number of military personnel overseas (all ages inclusively) is available for each year cited in the US Bureau of the Census report (1975), there is no reliable data on the age-structure of military personnel overseas for 1940-59. Fortunately, however, the US Bureau of the Census (1974) provides the 'total number of military personnel overseas by single years of age' for 1960-73. So, multiplying the average percentage distribution of these fourteen years by the total number of military personnel overseas (all ages inclusive), the total number of military personnel overseas by single years of age for 1940-59 can be estimated.

[^11]Another factor to consider in our calculations is the inconsistency of the data within the US Bureau of the Census volumes (1965, 1974, 1982, 1993, 2001). Two of the five volumes cite different total population figures for 1970-73, 1980-81 and 1990-91. This discrepancy is owed to the Bureau's revisions of its estimates in later volumes based on updated information. As a result, the data from later volumes is used for these years.

Yet, due to the inconsistency mentioned above, there remain 'jumps' in the annual data of the total population at three points — between 1959 and 1960; 1969 and 1970; 1979 and 1980; and 1989 and 1990. In order to smooth out these jumps, the data of these five volumes are used only for getting each age cohort percentage in the total population (all ages inclusive). For the annual data of the total population (all ages inclusive), a long-term data series is determined from Series A-7 of US Bureau of the Census (1975) and from various issues of Statistical Abstract of the United States. By multiplying this total population with those percentages, the total population by single years of age for 1900-2000 is calculated.

## 1890-1899

Based on the 'total population by single years of age' for 1900, which is found above, this paper estimates those for pre-1900 years. First, this paper estimates 'total population by single years of age' for 1890. One possible way is taking each cohort's population fluctuation rate between 1890 and 1900 from the censuses and multiplying it with its corresponding age's total population as of 1900; more precisely, let:
$G_{v, t}=$ This paper's estimate of the total number of persons aged $v$ years in year $t$ ( $G_{v, 1900}$ is already obtained above); and
$C_{v, t}=$ Census's datum of the total number of persons aged $v$ years in year $t$.
Then,

$$
\begin{equation*}
G_{V, 1890}=G_{V+10,1900}\left(\frac{C_{V, 1890}}{C_{V+10,1900}}\right) \quad(V=15, \ldots, 64) \tag{11}
\end{equation*}
$$

However, considering the 'every-5-year' problem, equation (11) may be somewhat insecure. So, instead of equation (11), this paper uses the following equation.
(12) $\quad G_{V, 1890}=G_{V+10,1900}\left(\frac{\sum_{k=V-2}^{V+2} C_{k, 1890}}{\sum_{k=V+8}^{V+12} C_{k, 1900}}\right) \quad(V=15, \ldots, 64)$

For 1891-99, assuming the total population of each cohort decreases in a constant rate for ten years, this paper estimates the total population by age from the following equation:

$$
\begin{equation*}
G_{V, t}=G_{V-t+1890,1890}\left(\frac{G_{V-t+1900,1900}}{G_{V-t+1890,1890}}\right)^{\frac{t-1890}{10}} \quad(V=15, \ldots, 64 ; \quad t=1891, \ldots, 1899) \tag{13}
\end{equation*}
$$

### 5.2 Enrollment Data

Two institutes officially conduct nationwide enrollment surveys. One is the US Office of Education, and the other is the US Bureau of the Census. The survey method of each differs significantly. While the US Office of Education collects enrollment data mainly from school surveys, the US Bureau of the Census collects it mainly from individual surveys. These differing methods produce different enrollment figures.

After due consideration, this paper chooses to use decennial censuses as the main data source for enrollment ratio. The main reasons for this choice are: (1) censuses cite enrollment surveys as early as the 1840 census, while the US Office of Education's data starts in 1870; and (2) censuses have more complete information on the age-distribution of total enrollment.

Yet there are some limitations to the censuses' enrollment data that require special consideration in this study. The most significant problem is that censuses data are available only for every tenth year. It is only for after 1988, the Bureau of Census provides annual enrollment data based on sampled survey (except for 1993). In this paper, as described below, enrollment ratios for census years between 1830 and 1988 is first estimated, and then linear interpolations are taken for inter-census years. For 1981-87 and 1993, this paper takes linear interpolations.

Although the majority of US children enter primary school at age 6, some do so at younger or older ages. At the same time, it is not uncommon for middle-age or elder people to go back to school. For the sake of simplicity, however, this paper assumes that the enrollment ratio for persons not of an age between 6 and 34 years is zero.

The following provides details of this paper's treatment of the censuses' enrollment data.

### 5.2.1 Total enrollment ratio

1960, 1970, 1980, 1988-92 and 1994-2000
For these years, the US Bureau of the Census provides the enrollment ratios of age groups by single years of age for persons aged under 25 years and by 5-year age groups (e.g., 25-29) for persons aged over 24 years (the US Bureau of the Census [1961, 1973, 1984] and its website). We must thus divide the total enrollment for the 25 to 29-year-old group among five separate years and repeat the process for the 30 to 34 -year-old group.

The enrollment ratio by single age for persons aged 25-29 years is calculated by solving equations (14-1) and (14-2) for $k$ (here, this paper assumes that enrollment ratio declines exponentially according to age).
(14-1) $R_{n}=R_{24} \times k^{n-24}$
(14-2) $\sum_{n=25}^{29}\left(R_{n} \times P_{n}\right)=R_{25-29} \times \sum_{n=25}^{29}\left(R_{n} \times P_{n}\right)$
where,
$R_{n}=$ Enrollment ratio for persons aged $n$ years ( $n=24, \ldots, 29$ );
$R_{25-29}=$ Enrollment ratio for persons aged 25-29 years; and
$P_{n}=$ Total number of persons aged $n$ years.
Then, using the solution for $R_{29}$ as a benchmark, this paper extrapolates for persons aged $30-34$ by solving equations (15-1) and (15-2) for $k$.
(15-1) $\quad R_{n}=R_{29} \times k^{n-29}$
(15-2) $\sum_{n=30}^{34}\left(R_{n} \times P_{n}\right)=R_{30-34} \times \sum_{n=30}^{34} P_{n}$
where,
$R_{n}=$ Enrollment ratio in persons aged $n$ years ( $n=29, \ldots, 34$ );
$P_{n}=$ Total number of persons aged $n$ years; and
$R_{30-34}=$ Enrollment ratio for persons aged 30-34 years.
1950
The 1950 census cites the enrollment ratio by single years of age for persons aged under 30 years but not for persons aged over 29 years. Assuming that enrollment ratios for persons aged over 29 years changed at the same proportion as that for persons aged 29 years, the enrollment ratio by single years of age for 29 to 34 -year-olds is estimated with the following equation (16).
(16) $\quad R_{n, 1950}=\frac{R_{29,1950} \times R_{n, 1960}}{R_{29,1960}}$
where,
$R_{n, t}=$ Enrollment ratio for persons aged $n$ years in year $t(n=29 \sim 34$, $t=1950,1960$ ).

The 1940 census cites enrollment ratio by single years of age for persons aged under 25 years but not for persons aged over 24 years. Assuming that enrollment ratios for persons aged over 24 years changed in the same proportion as that for persons aged 25 years, the enrollment ratio by single years of age for 25 to 34 -year-olds is estimated with the following equation (17).

$$
\text { (17) } \quad R_{n, 1940}=\frac{R_{24,1940} \times R_{n, 1950}}{R_{24,1950}}
$$

where,

$$
\begin{aligned}
& R_{n, t}=\text { Enrollment ratio for persons aged } n \text { years in year } t(n=24, \ldots, 34 \text {, } \\
& t=1940,1950) .
\end{aligned}
$$

## 1910, 1920, and 1930

The 1910, 1920 and 1930 censuses cite the enrollment ratio by single years of age for persons aged under 21 years. The total enrollment of persons aged over 20 years is also surveyed. The enrollment ratio by single years of age for 21 to 34-yearolds is estimated by solving equations (18-1) and (18-2) for $k$.
(18-1) $\quad R_{n}=R_{20} \times k^{n-20}$
(18-2) $\quad \sum_{n=21}^{34}\left(R_{n} \times P_{n}\right)=E_{21+}$
where,
$R_{n}=$ Enrollment ratio for persons aged $n$ years ( $n=20, \ldots, 34$ );
$P_{n}=$ Total number of persons aged $n$ years; and
$E_{21+}=$ Total enrollment of persons aged over 20 years.

## 1890 and 1900

In the 1890 and 1900 censuses, the enrollment ratio is surveyed in four age groups; persons aged 5-9 years, 10-14 years, 15-20 years, and over 20 years. In this paper's estimation of enrollment ratio by single years of age, extra efforts were made to get a reasonably well-shaped age-distribution curve (the age-distribution curves of this paper's estimates are shown in Figure 1). After much trial and error, the following data treatments are determined.
[Figure 1]
For persons aged 6-9 years, this paper estimates the ratios by solving
equations (19-1) and (19-2) for $k$ :
(19-1) $\quad R_{n}=R_{10} \times\left(1-k^{n-4}\right)$
(19-2) $\quad \sum_{n=5}^{9}\left(R_{n} \times P_{n}\right)=E_{5-9}$
where,
$R_{n}=$ Enrollment ratio for persons aged $n$ years ( $n=5, \ldots, 10$ );
$P_{n}=$ Total number of persons aged $n$ years; and
$E_{5-9}=$ Total enrollment of persons aged 5-9 years.
For persons aged 10-20 years, this paper uses equations (20) and (21).
(20) $\quad R_{n, t}=\frac{R_{n, 1910} \times R_{10-14, t}}{R_{10-14,1910}} \quad($ for $\quad 10 \leq n \leq 14)$
(21) $\quad R_{n, t}=\frac{R_{n, 1910} \times R_{15-20, t}}{R_{15-20,1910}} \quad($ for $\quad 15 \leq n \leq 20)$
where,
$R_{n, t}=$ Enrollment ratio for persons aged $n$ years in year $t(n=10, \ldots, 20$;
$t=1890,1900,1910$ );
$R_{10-14}=$ Enrollment ratio for persons aged 10-14 years in year $t$; and
$R_{15-20}=$ Enrollment ratio for persons aged 15-20 years in year $t$.

For persons aged over-20 years, we solve equations (22-1) and (22-2) for $k$.
(22-1) $\quad R_{n}=R_{20} \times k^{n-20}$
(22-2) $\quad \sum_{n=21}^{34}\left(R_{n} \times P_{n}\right)=E_{21+}$
where,

$$
R_{n}=\text { Enrollment ratio for persons aged } n \text { years ( } n=20, \ldots, 34 \text { ); }
$$

$P_{n}=$ Total number of persons aged $n$ years; and
$E_{21+}=$ Total enrollment of persons aged over-20 years.

## 1850, 1860, 1870, and 1880

Before describing this paper's data treatments in detail, it would be helpful to overview how enrollment data was collected in the 19th-century censuses.

The 1840 census was the first to collect enrollment data across the nation. Lacking clear direction on the methodology of data collection, marshals were forced to collect the total enrollment of their own jurisdictions. According to Folger and Nam (1967), enrollment data in the 1840 census was collected mainly by school survey and partly by individual survey.

Starting with the 1850 census, the Bureau prepared more stipulated directions for marshals. In the 1850, 1860, 1870 and 1890 censuses, total enrollment was surveyed in two different ways (accordingly, there are two different numbers for total enrollment)- one by school survey and the other by individual survey. In the 1880 census, however, the data was collected only by public school survey. Since private school survey was not included in the 1880 census, the total enrollment figure for that year is said to be underestimated by 1.2 million (Folger and Nam [1967]). Starting with the 1900 census, enrollment data has been collected only by individual survey.

After due consideration, the author decided to use data from school surveys for $1850,1860,1870$, and 1880 . Based on the aforementioned underestimation in the 1880 census, this paper adds 1.2 million to the total enrollment (all ages inclusive) for that year.

In the censuses prior to 1890, age distribution of the total enrollment is not surveyed in either schools or by individuals. By thus assuming that the enrollment ratio changed proportionally among all age groups and also using the data in the 1890 census as a benchmark, the enrollment ratio by single years of age is estimated with the following equation (23):

$$
\begin{equation*}
R_{n, t}=R_{n, 1890}\left(\frac{\frac{E_{t}}{P_{5-20, t}}}{\frac{E_{1890}}{P_{5-20,1890}}}\right) \tag{23}
\end{equation*}
$$

where,
$R_{n, t}=$ Enrollment ratio for persons aged $n$ years in year $t(t=1850,60,70$;
$n=6, \ldots, 34$ );
$E_{t}=$ Total enrollment in year $t$ (all ages inclusive); and
$P_{5-20, t}=$ Total number of persons aged 5-20 years in year $t$.

## 1830 and 1840

Because of data limitations, the total number of persons of age 5-20 years prior to 1850 is not available; only the total number of whites of age $5-20$ years is available for both 1850 and 1840. The enrollment ratio in 1840 is thus estimated with the following equation (24):

where,
$R_{n, t}=$ Enrollment ratio for persons aged $n$ years in year $t(t=1850,60$,
70; $n=6, \ldots, 34$ );
$E_{t}=$ Total enrollment (all ages inclusive); and
$W_{5-20, t}=$ Total number of whites aged 5-20 years in year $t$.

While no enrollment survey is included in the 1830 census, Cremin (1980) argues that 35 percent of whites aged 5-20 years were enrolled in schools around 1830. Based on his argument, and assuming that non-whites’ enrollment ratio is zero (i.e. $E_{1830} / W_{5-20,1830}=0.35$ ), this paper uses equation (24) for $t=1830$, too.

## Enrollment ratio for 1981-87, 93, and inter-census years during 1830-1980

For these years, this paper takes linear interpolations on enrollment ratio by single years of age. ${ }^{16}$

## Enrollment ratio by gender

Most of the data mentioned above are available by gender. In principle, then, the same calculations are done for males and females. There are some exceptions, however. First, since enrollment data for 1830 and 1840 is not available by gender, this paper assumes that the ratio between boys' and girls' enrollment is constant for 1830-50. ${ }^{17}$ Second, to calculate girls' enrollment ratio in 1970, equations (14-1') and (14-2') are used instead of (14-1), (14-2), (15-1), and (15-2) because the value of $k$ in (15-1) becomes more than 1.0 :

[^12](14-1') $\quad R_{n}=R_{24} \times k^{n-24}$
(14-2') $\sum_{n=25}^{34}\left(R_{n} \times P_{n}\right)=R_{25-34} \times \sum_{n=25}^{34} P_{n}$
where,
$R_{n}=$ Enrollment ratio for persons aged $n$ years ( $n=24, \ldots, 34$ );
$R_{25-29}=$ Enrollment ratio for persons aged 25-34 years; and
$P_{n}=$ Total number of persons aged $n$ years.

### 5.2.2 Enrollment ratio by levels of education

The previous subsection discussed the total enrollment ratio of all levels inclusive.

This subsection separates the total enrollment ratio into those of the three levels of education: primary, secondary and tertiary.

1960, 1970, 1980, and 1988-92 1994-2000
For these years, the US Bureau of the Census (1965, 74, 82 and website) provides the enrollment ratios according to every single grade. For persons aged under 25 years, for which enrollment ration is available by single years of age, this paper uses the Bureau's data with no adjustment. For persons aged over 24 years, for which enrollment data are available only for 5 -year age groups, this paper assumes that the percentage composition among primary, secondary and tertiary is constant in a 5-year age group.

1950

For persons aged under 30 years, this paper uses the 1950 census's data on enrollment by levels of education with no adjustment. For persons over 29 years, for
which we newly estimated the total enrollment ratio at Section 5.2.1, this paper assumes that the composition rates of three levels of education in the total enrollment are constant for all single age groups between 29 and 34 year-olds.

In the 1940 census, respondents were not asked "the grade (year of school) in which they are enrolled" but asked "highest grade of school completed". Thus, total enrollment is cited not "by single years of school (i.e. grades) enrolled" but "by single years of school (i.e. grades) completed". However, a considerable number of respondents were supposed to have answered their current enrollment level by mistake. According to Folger and Nam (1967), one-third of the people answered their current grade by mistake. Thus, in this paper, enrollment data for grade n in the 1940 census (denoted by $N_{n, 1940}^{\prime}$ ) is adjusted by the following equation.

$$
\begin{equation*}
N_{n, 1940}=\frac{2 N_{n, 1940}^{\prime}+N_{n+1,1940}^{\prime}}{3} \tag{25}
\end{equation*}
$$

Enrollment data in the 1940 census are limited for persons aged under 25 years. For persons aged over 24 years, for which this paper newly estimated the total enrollment ratio at Section 5.2.1, this paper assumes that the composition rates of three levels of education in the total enrollment are constant for all single age groups between 24 and 34 year-olds.

## Prior to 1940

## $\underline{\text { Basic Idea }}$

Because there had been no systematic individual survey conducted on educational level before the 1940 census, data processing becomes more complicated compared with the 1940 census and thereafter.

Before discussing data sources, it would be helpful to outline the basic procedure of estimation. First, this paper estimates the total enrollment of primary, secondary, and tertiary (all ages inclusive). These three enrollments are denoted as $N P, N S$, and $N T$ respectively hereafter. Then, this paper solves $i, j, x$, and $y$ that satisfy the following simultaneous equations (26-1), (262 ), (26-3) and (26-4) ( $i$ and $j$ are natural numbers; $x$ and $y$ are real numbers)

$$
\begin{aligned}
& \text { (26-1) } \quad \frac{\sum_{v=6}^{i-1} G_{v} R_{v}}{\sum_{v=6}^{34} G_{v} R_{v}}<\frac{N P}{N P+N S+N T}<\frac{\sum_{v=6}^{i} G_{v} R_{v}}{\sum_{v=6}^{34} G_{v} R_{v}} \\
& \text { (26-2) } \frac{N P}{N P+N S+N T}=\frac{G_{i} x+\sum_{v=6}^{i-1} G_{v} R_{v}}{\sum_{v=6}^{34} G_{v} R_{v}} \\
& (26-3) \quad \frac{\sum_{i=6}^{j-1} G_{v} R_{v}}{\sum_{u=6}^{34} G_{v} R_{v}}<\frac{N P+N S}{N P+N S+N T}<\frac{\sum_{i=6}^{j} G_{v} R_{v}}{\sum_{v=6}^{34} G_{v} R_{v}} \\
& (26-4) \quad \frac{N P+N S}{N P+N S+N T}=\frac{G_{j} y+\sum_{v=6}^{j-1} G_{v} R_{v}}{\sum_{v=6}^{34} G_{v} R_{v}}
\end{aligned}
$$

where, $G_{v}=$ Total number of persons aged $v$ years; and

$$
\begin{aligned}
& R_{v}=\text { Enrollment ratio for persons aged } v \text { years (all the levels inclusive; as found in the } \\
& \text { previous subsection). }
\end{aligned}
$$

Finally, the enrollment ratio by levels of education and by single years of age from 6 to 34 years is estimated as follows $\left(P R_{w}, S R_{w,} T R_{w}\right.$ are "primary school enrollment ratio for persons aged $w$ years," "secondary school enrollment ratio for persons aged $w$ years," and "tertiary school enrollment ratio for persons aged $w$ years" respectively).

For $w<i, P R_{w}=R_{w}, S R_{w}=0, T R_{w}=0$;

For $w=i, P R_{w}=x, S R_{w}=R_{w}-x, T R_{w}=0$;

For $i<w<j, P R_{w}=0, S R_{w}=R_{w}, T R_{w}=0$;

For $w=j, P R=0, S R_{w}=y, T R_{w}=R_{w}-y$; and

For $w>j, P R=0, S R_{w}=0, T R_{w}=R_{w}$.

Now, the next problem is how to estimate $N P, N S$ and $N T$. The precise data sources and this paper's procedure of data processing are given below.

1890, 1900, 1910, 1920, and 1930

Enrollment by levels of education (all ages inclusive) is available from school surveys of the US Office of Education (summarized in the US Bureau of the Census (1975)). Since there is a small difference in total enrollment between the US Office of Education's statistics and the censuses', this paper takes the ratio between the two. Using this ratio as a multiplier, this paper obtains $N P, N S$ and $N T$ that are consistent with the total enrollment in the censuses.

1830, 1840, 1850, 1860, 1870, and 1880

For these years, enrollment data for primary education are very limited. Thus, this paper estimates the total enrollment of secondary and tertiary education at first as below.

Total enrollment of tertiary education

As for 1870 and 1880, the total enrollment of tertiary education is available from the US Office of Education's statistics (cited in the US Bureau of the Census (1975)). The 1840, 50, and 60 national censuses provide the total enrollment in universities and colleges.

According to Cubberley (1934, p.140), the number of universities increased from 60 in 1930 to 98 in 1940. Assuming that enrollment per school is constant between 1830 and 1840, the
total enrollment of tertiary education is estimated for 1830.

## Total enrollment of secondary education

While the US Office of Education's data of the total enrollment of secondary education are available for 1890 and thereafter only, the data of the number of high school graduates are available as far back as 1870 . This paper estimates the total high school enrollment for 1870 and 1880 based on the number of high school graduates. First, the following equation is derived by an OLS regression.

$$
\begin{equation*}
E n r_{t}=0.295+1.021 \text { Grad }_{t} \quad R^{2}=0.997 \quad(t=1890,1900,1910,1920,1930) \tag{27}
\end{equation*}
$$

where,
$\operatorname{Grad}_{t}=$ Summation of the number of graduates from year $t$ to $t+3$; and
$E n r_{t}=$ Enrollment in grades 8-12 in year $t$.

Then, inserting the numbers of graduates from high school from 1870 to 1873 and from 1880 to 1883 in equation (27), $E n r_{1870}$ and $E n r_{1880}$ are estimated.

In the 1840 censuses, the total enrollment is emulated in three types of schools: "universities and colleges," "academies and grammar schools," and "primary schools." According to Cubberley (1934, p.140), English grammar school, Latin grammar school, and academy correspond to today's grades 4-12. Thus, this paper counts four-ninths of enrollment in academies and grammar schools as secondary education enrollment. For 1830, 1850, 1860, the total enrollment of secondary education is interpolated or extrapolated by a log-linear curve.

## Total enrollment of primary education

The total enrollment of the primary education is derived by subtracting the total enrollment of secondary and tertiary education (obtained above) from the total enrollment (all
levels inclusive).

## 6. Estimation results

### 6.1 Overview

Tables in Appendix D contain detailed results of this paper's estimation for Japan, Korea and the US. This section overviews the major results.

## [Table 7]

Table 7 summarizes educational investment and stock in the three countries. There, educational investment is measured by the total enrollment ratio for the schooling-age population (ages 6-20). As can be seen, the initial huge gap among the three countries diminished sharply throughout the 20th century. As of 2000, the average years of schooling in the US is 1.5 years higher than in Japan and 3.5 years higher than in Korea. However, there are no significant differences in total enrollment ratio among the three countries. This means that the gaps among those countries in the average years of schooling are expected to diminish with time.
[Tables 8-1, 8-2, and 8-3]

A similar pattern is found for the gender gap in education in Japan and Korea as is shown in Tables 8-1, 8-2 and 8-3. These two countries had huge educational gender gaps both in flow and in stock terms. However, the gender gap in enrollment was almost dissolved in 1950 in Japan and in 1960 in Korea. Females’ average years of schooling are still lower than males’ in 2000. But the gap has reduced to less than 1.0 year in both the countries. For the US, there has been no gender gap throughout this paper's estimation period.
[Table 9]

Table 9 shows average years of schooling in the working-age population by levels of education. While this paper assumes grades 1-8 as primary education and grades $9-12$ as secondary education, average years of schooling of primary and secondary education can exceed 8 and 12 respectively because average years of schooling in this paper include repetition years.

In the US, the average years of schooling of primary education already reached almost 8 in 1920 and have been over 8 thereafter. This means that primary education has been universal and repetition has not been rare since the latter half of the $19^{\text {th }}$ century in the US. The average years of schooling of secondary education is close to 4 in 2000, which means that high school education is now almost universal in the US.

As for Japan, average years of schooling of primary and secondary education have almost caught up with the US in 2000. However, Japan’s stock of higher education is still less than 50 \% of that of the US.

Korea's average years of schooling of primary education in 2000 is still around 7 years, nearly one year less than the other countries' level. This is because the older generations in

Korea did not have good accessibility even to primary education in their childhood. Today, Korea is known as one of the most enthusiastic countries in the world about education. With time, the new generations will take over the older generations, and Korea will catch up with the US in all the levels of education.
[Table 10]

Table 10 presents enrollment and average years of schooling of vocational education in Japan and Korea (as discussed in Section 2.3.3, this paper could not find enough information to estimate vocational education stock for the US). Because of the heavy investment in vocational education in the prewar period, Japan was endowed with rich vocational education stock throughout the high growth era (in the 1950s and the 1960s). The enrollment of vocational education in Korea increased sharply till 1990 and turned to be on a downward trend since the Asian Financial Crisis in 1997. Korea's vocational education stock still keeps increasing because the past increasing trend in enrollment of vocational education still affects the movement of vocational education stock.

This paper's study on vocational education has some limitations, too. For example, this study does not cover the informal vocational training institutions that are not authorized by the Ministry of Education. In particular, for Korea, young males receive vocational training in their 2.5 -year compulsory services in military camps. The treatment of this military training will be a key issue for the author's future studies.

### 6.2 Comparison with existing estimates on education stock

For the postwar period, there exist several estimates on education stock. None of the earlier studies provides as detailed human stock data as this paper. Still, rough comparison with existing studies is informative for users of this paper's estimates.
[Figures 2-1, 2-2 and 2-3]

Figures 2-1, 2-2 and 2-3 compare this paper's average years of schooling in the working-age population (all levels of education and both gender inclusive) with education stock estimates by Kim and Lau (1995), Nehru, Swanson and Dubey (1995) and Barro and Lee (2000).

There are two discrepancies in definition of education stock among these four studies. First, Nehru, Swanson and Dubey (1995) and Barro and Lee (2000) use "net" enrollment by subtracting the number of repeaters from the original total enrollment data, while Kim and Lau (1995) and this paper use "gross" enrollment including number of repeaters. Second, while persons aged over 64 years are included in Berro and Lee’s education stock, those high-aged population are excluded from that of the others.

The second point of discrepancies brings a downward bias in Barro and Lee's estimates for countries where high-aged population has a greater portion in the total population because older generations' average years of schooling are generally lower than those of their younger counterparts. This effect is expected to be stronger for recent years and for richer countries because the world population, in particular in high-income countries, has been increasing in average age in the postwar period.

Barro and Lee's estimates show unusual movements for Japan (Figure 2-1) and for the US (Figure 2-3). According to Barro and Lee, education stock in Japan had been almost constant
between 1960 and 1975. Similarly, education stock in the US had been almost constant between 1970 and 1995. However, it is unreasonable to assume that these two countries had no growth in education stock in those periods. It is uncertain whether these stagnations in Barro and Lee's education stock are attributable only to the previously-mentioned 'aging effect.' It is also possible that some other estimation errors affect Barro and Lee's estimates. In any case, Figures 2-1 and 2-3 imply that special attentions will be necessary if researchers try to measure education stock growth for Japan and the US from Barro and Lee's dataset.

Barro and Lee's estimates for Korea also show unusual movements in two senses (Figure 2-2). First, according to Barro and Lee, education stock for persons aged over 14 years decreased between 1965 and 1970. Second, in spite of the 'aging effect,' Barro and Lee's estimates are not at lower levels than those of the others. Here, again, it is difficult to specify the reasons of those unusual movements in Barro and Lee's estimates.

Nehru, Swanson and Dubey's estimates for Korea are almost same as those of this paper and Kim and Lau. However, Nehru, Swanson and Dubey's estimates for Japan and the US are different from any other. According to Nehru, Swanson and Dubey, Japan's and the US's education stock increased only 1.0 year between 1960 and 1987. This slowness in education stock growth obviously contradicts the commonsense of a majority of researchers. However, Nehru, Swanson and Dubey provide no reasoning for it.

Kim and Lau present similar estimation results to those of this paper for Japan and Korea ${ }^{18}$. For the US, Kim and Lau's estimate for 1950 is at almost one year less than that of this paper. The two series converge to the almost same level in 1990. Kim and Lau use the US 1950 census's data of average years of schooling as a benchmark. Since the census's average years of schooling are measured by "net" enrollment, Kim and Lau’s estimate for 1950 has a lower bias. This bias is gradually eliminated according to time because they accumulate "gross" enrollment for 1951-90. It may be legitimate to argue that this paper's data treatment is more consistent than Kim and Lau's because this paper uses only "gross" enrollment for all the estimation years.

## 7. Conclusion

This paper's dataset of education stock has several advantages over existing popular datasets such as Kim and Lau (1995), Nehru, Swanson and Dubey (1995) and Barro and Lee (2000). First, this paper’s estimation period is much longer than any other existing studies. Second, this paper provides very detailed estimates of average years of schooling according to gender, age groups, and types and levels of education. Third, this paper's estimates are based on exhaustive works in collecting original data sources and careful data processing, which guarantees the accuracy of estimation results.

The author's dataset is so vast that only a portion is included in this paper. The author can provide further details of the dataset on request. Invention of new indicators for education stock is also possible based on the author's dataset.

The author is now extending the coverage of dataset to Taiwan, the Philippines and

[^13]Thailand. The author hopes that future researchers use the author's dataset as a "public good" to analyze the macroeconomic role of education.

## Appendix A. Physical capital data

## A. 1 Definition and estimation method

Capital stock in this paper is defined as gross non-residential fixed capital (excluding that for military use) at the beginning of the year measured in 1990 US dollars (PPP exchange rate). This paper employs the perpetual inventory method. This paper uses some of the existing estimates after making special adjustments according to this paper's definition of capital stock. If those existing estimates use the year-end basis, this paper treats them as the estimates of the beginning for the next year.

## A. 2 Japan

1955-2000

Because of data availability, this paper estimates public and private capital stock separately at "fiscal year ends" at first (a Japanese fiscal year $t$ starts on April 1 in the calendar year $t$ and ends on March 31 in the calendar year $t+1$ ). Then, this paper transforms them into those at the beginning of the calendar year by the following equation.
$(\mathrm{A}-1) \quad \ln S_{t}=0.25 \ln \left(P R I Y_{t-1}+P U B Y_{t-1}\right)+0.75 \ln \left(P R I Y_{t-2}+P U B Y_{t-2}\right)$
where,
$S_{t}=$ Total capital stock at the beginning of calendar year $t$;
$P R I Y_{t}=$ Private capital stock at the end of fiscal year $t$; and
$P U B Y_{t}=$ Public capital stock at the end of fiscal year $t$.

Then, using OECD’s (1999) PPP estimate for Japanese yen in 1990, this paper evaluates $S$ in equation (A-1) in the US 1990 dollars.

## Private capital

Japan Economic Planning Agency (1998a, 2000) provides the data of private capital stock at 1990 prices for 1955-1998 fiscal years. Japan Economic and Social Research Institute
(2002) provides those at 1995 prices for 1990-2000 fiscal year. The latter data are spliced to the former data by the following OLS regression for 1990-98 fiscal years.

$$
\begin{equation*}
\ln S^{\prime}=-1.47+1.07 \ln S^{\prime \prime} \quad R^{2}=0.999 \tag{A-2}
\end{equation*}
$$

where,
$S^{\prime}=$ Private capital stock data from Japan Economic Planning Agency (2000); and
$S^{\prime \prime}=$ Private capital stock data from Japan Economic and Social Research Institute (2002)

## Public physical capital

Japan Economic Planning Agency (1998b) provides the data of gross investment and stock of public capital at 1990 prices for 1953-93 fiscal years. ${ }^{19}$ Japan Cabinet Office DirectorGeneral of Policies (2002) provides the same data at 1995 prices for 1953-1998. Since this paper employs 1990 as the base year of price level, this paper uses Japan Economic Agency’s data as the baseline. Then, this paper extrapolates the stock data up until 1998 fiscal year by the following OLS regression:

$$
\begin{equation*}
\ln S_{a}=-0.479+1.02 \ln S_{b} \quad R^{2}=0.993 \tag{A-3}
\end{equation*}
$$

where,
$S_{a}=$ Public stock data from Japan Economic Planning Agency (1998b); and
$S_{b}=$ Public stock data from Japan Cabinet Office Director-General of Policies (2002).

[^14]According to the investment and stock data from Japan Cabinet Office DirectorGeneral of Policies (2002), the average depreciation rate for public capital between 1953 and 1998 fiscal year is $0.00541^{20}$.

This paper extrapolates the investment data from Japan Cabinet Office DirectorGeneral of Policies (2002) to 1999 fiscal year by splicing capital formation data from Japan Economic and Social Research Institute (2003) with investment data from Japan Cabinet Office Director- General of Policies (2002) as follows. ${ }^{21}$
(A-4) $\quad \ln I_{b}=-0.417+1.03 \ln I_{c} \quad R^{2}=0.993$
where,
$I_{b}=$ Public investment data from Japan Cabinet Office Director-General of Policies (2002); and
$I_{c}=$ Public capital formation data from Japan Economic and Social Research Institute $(2003)^{22}$.

Applying the above-obtained investment data with the average depreciation rate, this paper extends the data of public capital stock for 1999 fiscal-year end, and substitutes the value for $S_{b}$ in equation (A-3) in order to estimate capital stock for 2000.

[^15]
## Prior to 1955

This paper applies the perpetual inventory method by accumulating annual investment and retirement starting at 1832 .

Investment data for 1832-1954

## From 1935 to 1954

Japan Economic Planning Agency (1965) provides investment data for 1935-44 calendar years and 1946-63 fiscal years. ${ }^{23}$ Japan Economic Planning Agency (1965) provides the deflator of 1935-base and nominal values.

First, the 1935-base must be converted to the 1990-base. The Japan Economic Planning Agency does not publish the 1990-base deflator for pre-1970 years. Instead, they publish the 1935-base deflator for 1955-89 in Japan Economic Planning Agency (1991). This paper converts the 1985-base real values to the 1990-base real values by the following equation:

$$
\begin{equation*}
S_{90, t}=\frac{S_{35, t} \sum_{i=1963}^{1955} D_{35, i}}{D_{90,1985} \sum_{i=1963}^{1955} D_{85, i}} \tag{A-5}
\end{equation*}
$$

where,
$S_{35, \mathrm{t}}=$ Capital stock in year $t$ at 1935 prices;
$S_{90, \mathrm{t}}=$ Capital stock in year $t$ at 1990 prices;
$D_{35, \mathrm{t}}=1935$-base deflator for capital formation expenditure in year $t$;
$D_{85, \mathrm{t}}=$ 1985-base deflator for capital formation expenditure in year $t$; and
$D_{90, \mathrm{t}}=1990$-base deflator for capital formation expenditure in year $t$.

For 1945, no data is available from Japan Economic Planning Agency (1965). This paper assumes that the investment in 1945 was the same amount of that in 1944.

[^16]
## From 1887 to 1909

Emi (1971) provides the investment data series for $1887-1940$ at 1935 prices ${ }^{24}$. This paper splices Emi’s estimates to the Japan Economic Planning Agency’s (1965) data for 1935-44 (used in equation A-5) based on the following OLS regression.

$$
\begin{equation*}
\ln E P A_{t}=-0.481+1.03 \ln E M I_{t} \quad R^{2}=0.923 \quad(\mathrm{t}=1935, \ldots, 1940) \tag{A-6}
\end{equation*}
$$

where,
$E P A_{t}=$ Japan Economic Planning Agency’s (1965) investment data for year $t$; and
$E M I_{t}=$ EMI's (1971) investment data for year $t$.

## From 1832 through 1886

This paper takes a semi-log-linear time-trend regression for 1887-1940 as follows.
(A-7) $\quad \ln I_{t}=-122.7+0.676 t \quad R^{2}=0.964$
where, $I_{t}=$ This paper's estimate for investment in year $t$.

Using this result, this paper extrapolates investment series for 1832-86.

## Estimation of retirement ratio for 1830-1955

The next problem is how to obtain the data for retirement ratio. The author could not find reliable information from the existing data sources. Thus, this paper tries to find the retirement ratio that matches this paper’s estimate of capital stock in 1955. Namely, this paper solves the following equation for $k$ (here, this paper assumes the war damage as 26.9 percent at the single year of destruction of capital stock in 1945; 26.9 percent is cited in Ohkawa and Rosovsky (1973)).

[^17]\[

$$
\begin{equation*}
S F_{1955}=0.731\left\{\sum_{t=1832}^{1945}(1-k)^{1955-t} I_{t}\right\}+1.25 I F_{1946}(1-k)^{1.25}+\sum_{t=1947}^{1955}(1-k)^{1955-t} I F_{t} \tag{A-8}
\end{equation*}
$$

\]

where,
$S F_{1955}=$ This paper's estimate for capital stock at the end of fiscal year 1955, which is found in the previous part of this subsection;
$k=$ Retirement ratio;
$I_{t}=$ Investment in calendar year $t$; and
$I F_{t}=$ Investment in fiscal year $t$.

Note that $S F_{1955}, I_{t}$, and $I F_{t}$ in equation A-8 are already estimated in the previous part of this subsection.

Then, applying this $k$ to all the years between 1832 and 1954, this paper estimates capital stock for all the pre-1955 years.

## A. 2 Korea

This paper relies on Pyo (2001) for Korea. Pyo's definition and estimation methodology match to this study. Table 27 in Pyo provides his estimates on the Republic of Korea's capital stock for 1946 and thereafter in 1990 won. This paper converted them into 1990 dollar base using OECD’s (1999) PPP exchange rate.

Pyo states that the capital stock in all Korea dropped 12.2 \% between 1945 and 46. Pyo also estimates that capital stock in the Southern part of Korea shared 43.05 \% of the total capital stock in the whole Korea in the end of the Pacific War. Thus, this paper estimates capital stock for all Korea for 1945 by multiplying the Republic Korea's capital stock as of 1946 with 2.039 ( $=0.4305 / 0.878$ ). Using these estimates for 1945 as benchmark, this paper estimated Korea’s capital stock for 1910-1944 using Pyo's estimates of capital stock for the prewar Korea (Table 20-1 in Рyo (2001)).

## A. 3 United States

For 1927-90, US Bureau of Economic Analysis (USBEA) (1993) provides satisfactory information on capital stock. There, annual data series of physical capital stock is calculated by means of the perpetual inventory method in the 1987 US dollars. More precisely, annual investment and retirement are accumulated starting in 1832 for which the initial stock level is assumed to be zero as a benchmark. This paper uses the USBEA's estimates after adjusting their price to the 1990 level by OECD's (1999) deflator for capital formation in the United States.

Because the USBEA changed the framework of capital stock estimates from
gross-base to net-base, there is no official stock data for 1990 and thereafter. This paper extends USBEA's data up until 2000 by estimating investment and depreciation ate.

This paper uses Economic Report of President 2002 for the data source of investment for the 1990s. Table B-19 and B-20 of this book provide estimates of capital formation measured in 1996 US dollars for 1987-2000. Private investment is taken by subtracting 'information processing equipment and software' from 'total nonresidential investment' in Table B-19. For public investment, Table B-20 in Economic Report of President 2002 provides the data of investment of the federal and local governments. However, the data in Table B-20 includes 'information processing equipment and software.' In order to subtract this portion from the total investment, this paper applies the ratio of 'information processing equipment and software' and 'structure' in private investment in Table B-19. This paper converts those investment data to those in 1990 US dollars based on OECD's deflator for capital formation.

Because of the difference of methodology and coverage, the above mentioned investment data do not exactly match to the USBEA's data. Namely, the new estimates from Economic Report of President 2002 are 10.2 \% higher than USBEA's investment data as a three-year average of 1987-89. Thus, this paper multiplies above-estimated data by 0.907 .

The average depreciation rate for 1928-89 in USDC is 2.76\%. Applying this figure and investment data obtained above, this paper extrapolates the USBEA's capital stock data up until 2000.

Pre-1926 years are somewhat problematic. For these years, the USBEA provides only investment data and neither capital stock nor retirement data is cited there.

In order to get physical capital stock data going back to 1870, this paper at first calculates the average retirement ratio for 1832-1924 by solving the following equation for $k$.

$$
S_{1926}=\sum_{t=1832}^{1925}(1-k)^{t-1832} I_{t}
$$

where,
$S_{1926}=$ Physical capital stock in 1926;
$k=$ Average retirement ratio for 1832-1925; and
$I_{\mathrm{t}}=$ Investment in year $t$.
Then, applying this $k$ to all the years between 1832 and 1925, this paper extrapolates physical capital stock data for pre-1926 years by the perpetual inventory method.

## Appendix B Labor data

## B. 1 Definition

This paper measures labor input by total employment. This paper also provides estimates of average working hours for available years.

## B. 2 Japan

Total employment for Japan is cited from Umemura et al. (1988) for $1872-1940^{25}$ and Japan Ministry of Health, Labour and Welfare (MHLW) (various issues, a) for 1948 and thereafter.

ILO (various issues) provides the data of average working weekly hours going back to 1947. However, this ILO series has a jump between 1954 and 1955. Thus, this paper takes an extrapolation by the data from MHLW (various issues, b). The MHLW provides two data series. One covers for 1950 and thereafter and the other covers 1947-50. The survey methodologies differ between the two. For 1950-54, this paper extrapolates ILO's data by the following regression for 1955-2000. ${ }^{26}$

$$
\begin{equation*}
\ln I L O=-1.91+1.08 \ln M H L W \quad R^{2}=0.999 \tag{B-1}
\end{equation*}
$$

where,
$I L O=$ ILO's data of average working weekly hours; and
$M H L W=$ The MHLW's data of average working weekly hours.

The thus-obtained estimate for 1950 is used as the benchmark for this paper's estimates for 1947-49. Assuming that the average working hours changed proportionally to the data of MHLW's 1947-50 series, this paper estimates the average working hours for 1947-49.

The information on average working hours for prewar Japan is very limited. Japan Statistics Association (1988) provides the average working hours at factories for 1923-44 (however, the figures for 1943 and 44 are irrationally so high that this paper does not try to estimate for those two years). By assuming that the average laborers worked 250 days per year and one year consists of 52 weeks, this paper estimates the average weekly working hours.

## B. 3 Korea

The data of total employment are available in ILO (various issues) and Pyo (2001). ILO also provides data of average working hours for 1963 and thereafter. However, ILO revised data for 1970-71 resulting in a discontinuity between 1969

[^18]and 1970. Fortunately, for 1970, both the estimates of before and after revision are available. Thus, this paper takes the ratio between the two and multiplies the old 1963-69 series with the ratio.

## B. 4 United States

For the United States, Economic Report of President 1991 and 2002 provide two series of total employment. One is measured as for persons aged over 15 years and covers 1947-1990. The other is measured as for persons aged over 13 years and covers 1929, 33, 39 and 40-47. By taking the ratio of the two series at 1947, the later is spliced to the former. For the remaining years, this paper employs Kendrick's (1965) data of the total employment, which covers 1874, 1884, and 1889-1954. Kendrick's data are spliced to those of Economic Report of President by the following log-linear regression ${ }^{27}$.
(B-2) $\ln ($ President $)=-0.235+1.021$ n (Kendrick) $R^{2}=0.981$
where,

> President $=$ Employment data from Economic Report of President; and
> Kendrick $=$ Employment data from Kendrick (1965).

ILO (various issues) provides data of average working hours for 1946 and thereafter. However, ILO revised data for 1960-63 resulting in a discontinuity between 1959 and 1960. Just as in the case of Korea, this paper takes the ratio between the revised data for 1960 and the former (before revision) data for 1960. Then, this paper multiplies the figures of the old 1946-59 series with the ratio. The US Bureau of the Census (1975) provides the data of average working hours for all the industries for 1914, 1920-48 in Series D-831. By splicing at 1946, this paper extended the above-obtained series to 1914 and 1920-45.

Series D-765 in the US Bureau of the Census (1975) provides the average working hour data for the manufacturing industry for 1890-1926. This pper splices Series D-765 to Series D-831 by the following regression:
$(\mathrm{B}-3) \quad \ln (D 831)=0.394+0.885 \ln (D 765) \quad R^{2}=0.580$
(2.88)
where,

$$
\begin{aligned}
& \text { D765 = Working hour data from Series D-765; and } \\
& \text { D831 }=\text { working hour data from Series D-831. }
\end{aligned}
$$

[^19]where $E=$ this paper's estimate for year $t$; interpolated $N_{t}=$ Data for year $t$ from Economic Report of President; and $N^{*}{ }_{t}=$ Estimated value based on equation B-2.

## Appendix C GDP data

## C. 1 Japan

OECD (1999) and Maddison (1995) provide long-term estimates of GDP in the 1990 PPP US dollars. The former covers 1960 and 1969-97 and the latter, 1885-1994. For 1960 and 1969-92, those two exhibit similar but not entirely same figures because of the difference in methodologies and data sources. In particular, for 1960, and 1969-70, Maddison's estimates are constantly 2.36 percent higher than OECD's (the reason for this difference is not clarified). Thus, this paper uses Maddsion's data after multiplying 1.0236 with them. Japan Economic and Social Research Institute (2002) gives GDP in 1995 yen for 1980-2000. This paper spliced OECD's data using the following regression.

$$
\begin{equation*}
\ln A=-5.06+0.978 \ln B \quad R^{2}=0.999 \tag{C-1}
\end{equation*}
$$

where,
$A=$ GDP data from OECD (1999); and
$B=$ GDP data from Japan Economic and Social Research Institute (2002).

## C. 2 Korea

For 1946-1999, Table 27 in Pyo (2001) provides GDP data. This paper extrapolates his data series up until 2000 using World Bank's (2003) estimates of GDP for Korea for 1960-2000. The relationship between the two series is expressed by the following equation.
$(\mathrm{C}-2) \quad \ln ($ Pyo $)=-0.197+1.01 \ln (W B) \quad R^{2}=0.9997$
(-2.55) (284.3)
where,

Pyo = GDP data from Pyo (2001); and
$A B=$ GDP data from World Bank (2003).
Using this regression result, this paper splices the World Bank’s GDP data to Pyo’s up until 2000.
Table 27 in Pyo (2001) is measured in 1990 won. This paper uses OECD's GDP estimates for 1990 as a benchmark. OECD estimates 333.8 billion dollars and Pyo estimates 179,539 billion won. Taking the ratio between the two, this paper obtains the converter (0.001859) for the postwar period.

For the prewar period, this paper uses Pyo’s estimates of NNP at 1934-36 Chosen yen (Table 18-1 in Pyo (2001)) ${ }^{28}$. According to Ohkawa, Takamatsu and Yamamoto (1974) and Mizoguchi and Umemura (1988), the real NNP of Korea in 1935 was 12.1 percent of Japan staple's. On the other hand, this paper's estimate for Japan's GDP (estimated in Appendix B.1)

[^20]in 1935 is 0.138 billion in 1990 US dollars. Thus, Korea’s GDP in 1935 is calculated as 0.0169 (= 0.121 x 0.138) billion 1990 US dollars. Since Pyo's estimate for Korea’s NNP in 1935 is 2.015401 billion Chosen yen, this paper obtains the ratio of 0.00836 ( $=0.0169 / 2.015$ ) as the converter for Pyo's estimates of NNP for prewar Korea.

## C. 3 United States

Economic Report of President 2002 provide GDP data at 1997 prices for 1959-2000. OECD (1999) and Maddison (1995) provides long-term estimates on GDP data in the 1990 PPP US dollars. The former covers 1960 and 1969-97 and the latter, 1870-1994. This paper splices these series based on the following regressions.
$(\mathrm{C}-4) \quad \ln (O E C D)=0.964+0.8701 \mathrm{n}(N A) \quad R^{2}=0.9993$
(29.5) (224.0)
(C-5) $\quad \ln (O E C D)=1.33+0.9158 \ln ($ MAD $) \quad R^{2}=0.9997$
(13.1) (132.2)
where,
$O E C D=$ GDP data from OECD (1999);
$N A=$ GDP data from Economic Report of President 2002; and.
$M A D=$ GDP data from Maddison (1995).

Table D-1-1 Average years of schooling by gender and age group, Japan

|  | Both sexes |  |  | Male |  |  | Female |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

[^1]:    ${ }^{1}$ As will be mentioned later, this paper assumes that schooling is provided for persons of age 6 years and over. Thus, $N_{w, t}$ actually becomes zero for persons not of these ages.

[^2]:    ${ }^{2}$ The Okinawa Prefecture was returned to Japan in 1972. Thus, to interpolate for the years 1972-74, this paper adds Okinawa's population to the total population cited in the 1970 census. In the same way, to interpolate for 1971, this paper subtracts Okinawa's population from the total population of the 1975 census.

[^3]:    ${ }^{3}$ Although there are no accurate statistics, many Japanese population researchers argue that the pre-Meiji-era mortality rate (before 1868) is significantly larger than that during the Meiji era (for example, see Saito [1996]). Hence, the assumption of $M_{v, t}=M_{v, 1871}$ ( $v<64, t<1871$ ) would underestimate pre-Meiji-era mortality rates. In this sense, this paper's assumption about pre-Meiji-era mortality rates may result in an upward bias in this paper's estimates of average years of schooling. At the same time, however, this paper's assumption about pre-Meiji-era enrollments, as will be described in note 8 of this section, may bring a downward bias toward this paper's estimates of average years of schooling. This paper assumes that these two reciprocal effects cancel each other out.
    ${ }^{4}$ For 1972, the year in which Okinawa was returned to Japan by the United States, the total enrollment cited in Fundamental School Survey does not contain Okinawa’s statistics. Fortunately, however, Fundamental School Survey provides Okinawa's total enrollment by grade for 1972 as a reference. This paper adds Okinawa’s total enrollment to the Fundamental School Survey original data for 1972.

[^4]:    ${ }^{5}$ For 1941-45, which the Japan Bureau of Statistics (1970) does not cover, this paper takes log-linear interpolations with the Bureau's 1940 values and the national census's 1947 values.

[^5]:    ${ }^{6}$ Consulting with the annual reports of Japan Ministry of Education, the figures of 'Jinjo-Hoshu-ka Jido Su (total enrollment of supplementary course of ordinary primary school)' in 1886-90 prove to be those of 'Kan-i-ka Jido $S u$ (total enrollment of simplified course of ordinary primary school)'

[^6]:    ${ }^{7}$ According to National Institute for Educational Research (1973-74, Vol. 5, p.294), the number of students who were simultaneously enrolled in Jitsugyo-Hoshu-Gakko and Seinen-Kunrensho was a little more than 300,000 as of 1931 . This figure is almost equivalent to 60 percent of the total enrollment of Seinen-Kunrensho in 1931.

[^7]:    ${ }^{8}$ Although we are uncertain of how the survey was conducted, it is natural to expect that once the older Terakoya schools had been closed, it was less likely they were listed in Nihon-Kyoikushi-Shiryo. In this sense, the methodology of our estimates may underestimate the total enrollment in the early years. However, as discussed in Note 3, the author expects this paper's estimates of average years of schooling are free from systematic bias.

[^8]:    ${ }^{9}$ Precisely speaking, Shogakko Jinjo-Hoshu-ka before 1891, which is basically for persons aged 10-11 years, is classified into primary education according to this paper's definition mentioned in the section of 2.3.4.
    ${ }^{10}$ In these censuses, the age structure is reported for the total population (all races inclusive). Assuming that the age structure of Koreans is the same as that of the total population, the total Korean population by single years of age is estimated.

[^9]:    ${ }^{11}$ Before 1924, the schooling year of middle school was extended from 4 to 5 . Thus, this paper counts the enrollment of the first year of Senmon Gakko before 1924 as students aged 16 years. There were no reports of Korean enrollment in Yoka, Kanritsu Daigaku and Daigakuin before 1924.

[^10]:    ${ }^{12}$ Chosen Statisticsal Yearbook reports the total enrollment of Sodang all the ethnicities inclusively. This paper assumes only Koreans attended Sodang. As for Kakushu Gakko, Chosen Statistical Yearbook reports the total enrollment by ethnicity only for 1943 and thereafter (for pre-1943 years, the yearbooks report the total enrollment only all ethnicities inclusively). Assuming that Koreans' percentage in the total enrollment for pre-1943 years was the same as that of 1943, this paper estimates Koreans' enrollment in Kakushu Gakko for pre-1943 years.
    ${ }^{13}$ In collecting newspaper articles in the prewar period, the author got special assistance at the morgue of Dong-a Ilbo Newspaper Company at Seoul.
    ${ }^{14}$ These percentages were cited in an article of Dong-a Ilbo on May $27^{\text {th }}, 1939$.

[^11]:    ${ }^{15}$ All the enrollments before 1911 are assumed to be ar the primary level since the opportunities for secondary and tertiary education were quite limited in those years.

[^12]:    ${ }^{16}$ The author tried several means of interpolation, such as log-linear curves and logistic curves, none of which produced any significant differences.
    ${ }^{17}$ According to the 1850-90 census, the ratio between male and female enrollment ratios that are measured by 'total male (or female) enrollment' divided by 'the total number of males (or females) aged 5-20 years' was almost constant.

[^13]:    ${ }^{18}$ If we take the annual growth rate of Japan's education stock, however, we can find that Kim and Lau's series has abnormal jumps. This comes from their data sources for Japanese population for inter-census years. While the Japan Ministry of Home Affairs (MHA) provides the data of total population by age for non-census years, its estimates are inconsistent in time as this paper discussed in Section 3.2. Therefore, this paper takes log-linear interpolations on censuses' population data instead of using the MHA's data. However, Kim and Lau's choice is to use the MHA's data with no adjustment.

[^14]:    ${ }^{19}$ The classification between public and private physical capital in Japan Economic Planning Agency (1998a, 1998b, 2000) is totally consistent. For example, if a national enterprise was privatized (such as the case of Japan Railway in 1987), it became excluded from public physical capital in Japan Economic Planning Agency (1998b) and simultaneously included in private physical capital Japan Economic Planning Agency (1998a, 2000).

[^15]:    ${ }^{20}$ The data from 1985 and 1987 fiscal years are excluded from the average estimation. In these years, there were big changes in the categorization of the public capital because of the privatalization of the former Nippon Telegraph and Telephone Public Corporation and the former Japan National Railway.
    ${ }^{21}$ This regression is taken for 1980-98 fiscal years.
    ${ }^{22} I_{c}$ is measured at 1995 prices. The original data of public capital formation data series in Japan Economic and Social Research Institute (2003) include residential investment. This paper subtracts the residential investment from the total public capital formation by using the percentage composition of the public capital estimated in Table 3-39 in Japan Economic and Social Research Institute (2002b).

[^16]:    ${ }^{23}$ Precisely speaking, this paper obtains investment data by summing up expenditure for producer's durables (equipment and structures) and the government's capital formation.

[^17]:    ${ }^{24}$ Columns B-E of Table 3 in Emi (1971). These data are measured at the 1934-36 moving average prices.

[^18]:    ${ }^{25}$ Precisely, Umemura et al. (1988) provides yearend-base data for 1872-1920 and mid-year base data for 1920-40. This paper employs the mid-year-base. Umemura et al.'s data for 1872-1920 are converted into mid-year base by multiplying the ratio between the mid-year base figure and the yearend base figure as of 1920 .
    ${ }^{26}$ This paper used MHLW’s survey for companies of non-service industries with over-5 employees

[^19]:    ${ }^{27}$ For 1930-32 and 34-38, this paper took interpolation by the following equation:
    $\ln E_{t}=\frac{(t-1933)}{4}\left(\ln N_{1929}^{*}-\ln N_{1929}\right)+\frac{(t-1929)}{4}\left(\ln N_{1933}-\ln N_{1933}^{*}\right)+\ln N_{t}^{*} \quad(t=1930,31,32)$
    $\ln E_{t}=\frac{(t-1939)}{6}\left(\ln N_{1933}^{*}-\ln N_{1933}\right)+\frac{(t-1933)}{6}\left(\ln N_{1939}-\ln N_{1939}^{*}\right)+\ln N_{t}^{*} \quad(t=1934, \ldots, 38)$

[^20]:    ${ }^{28}$ While prewar Korea was annexed by Japan and used the currency 'yen' as Japan staple, the real value of Korean yen was not par. Thus, this paper expresses the unit of money in prewar Korea as 'Chosen yen.'

[^21]:    (continued)
