Compilation of the International Input-Output Table for the BRICs -A Feasibility Study-Asian International Input-Output Series, No.71, Institute of Developing Economies, JETRO, March 2008

Chapter 2

Developments of Russian Input-Output Tables

Masaaki Kuboniwa

Abstract

This chapter reviews the features of Russian input-output tables as well as the compilation history since the era of the Soviet Union. Although the Russian statistics authority has made efforts to compile the input-output table under the new accounting system that is consistent with SNA after the break-up of the Soviet Union, there still exist many problems such as timeliness and accuracy.

Keywords: Russia, MPS, SNA, input-output table

1. A Short History of Russian Input-Output Tables (IOTs)

1.1 The Soviet era

In the 1920's, shortly after the Russian Communist Revolution, an early form of input-output analysis was developed. The most notable achievement was the Balance Sheet of the National Economy of the USSR for 1923/1924, which was compiled by the Central Statistical Administration (TsSU) in 1926 (Popov ed., 1926). This included a balance of the production and use of the social products and national income, "chessboard" balance sheets of productive consumption and an investment balance sheet. The production and use of the social product was broken down into 4 sectors and 37 products. Construction and publishing were distinguished as independent sectors. Leontief's input-output table (IOT) can be constructed by merging the balance of production and use of the social product and the balance of national income. Therefore, we can state that the TsSU balance sheet served as a proto-type for the contemporary IOT. Further, the TsSU balance sheet also included the proto-type table for the capital matrix and the employment matrix. In the balance

sheet a distinction was made between transactions in producers' prices and purchasers' prices. In the TsSU monograph we can discern the fundamental concept of input-output analysis: "it is also important to clarify the relationship and interdependence between individual industry groups of the national economy."

It is well known that in a speech at a conference of agricultural experts in December 1929, Stalin referred to the pioneering balance of the national economy developed by TsSU as a "game with figures." Under the Stalin system further development of the balance could not be expected. Instead, Wassily W. Leontief, an immigrant from Russia, developed the compilation of IOTs for the American economy and its analytical tools in the United States.

Soon after Stalin's death, Soviet economics and statistics began to be released from the confines imposed by the cult of personality and dogmatism. Soviet authorities also approved the application of input-output analysis and the optimization theory to the centrally planned economies. In 1957 a preliminary version of the Soviet input-output table began to be compiled. The first Soviet benchmark IOT for 1959 was compiled by TsSU and partially published in 1961. The benchmark IOTs for 1966, 1972, 1977, 1982, and 1987 were compiled by TsSU. Since 1966 15 republican IOTs as well as the Soviet IOTs began to be compiled in the unique format by republican branches of the TsSU. In 1987 Gorbachev reorganized the TsSU and its republican branches as the State Committee of the USSRS (Goskomstat USSR) and its branches (Russian Goskomstat etc.) 1987 in order to improve the statistics. All of these IOTs were compiled based on the traditional Soviet methodology, namely material product system (MPS). Namely, they excluded "non-material services" (education, health care, finance, administration etc.) from the production sphere, while therein "material services" (freight transport, business communications, retail and wholesale trade and social catering) were considered to be components of value added.

1.2 The new Russian era

Since the break-up of the USSR the Russian Federation (Russia) received all assets-liabilities of the Russian and external territories from the USSR. Russian Goskomstat also placed the position of Goskomstat USSR. The new Russia's main economic policy has targeted the transition to a market economy. The main task of the statistics bureau has been the conversion of the Soviet methodology, MPS into the international standard, SNA (more precisely "SNA 1993"). In 1992 Russian Goskomstat began to compile preliminary versions of SNA IOTs. This effort resulted in preliminary SNA IOTs for 1991, 1992 and 1993 with 22 production sectors where non-material services were included into the production sphere.

The Russian Federal Government decided in April 1995 that the benchmark SNA IOT for 1995 should be completed by September 1997. In accordance with this decision Goskomstat submitted the first version of 1995 IOT to the Russian cabinet at

the beginning of September 1997. This system of IOTs had epoch-making characteristics: (1) they were the first large-scale IOT system for the new Russia based on fundamental research, survey input data and other important sources; (2) they were the first benchmark IOT ever created in Russia based on the System of National Accounts (SNA) developed by the United Nations and other international organizations; and (3) they were probably the world's first benchmark IOT produced in accordance with SNA 1993, the most updated version of the SNA (UN et al.,1993). However, the first version of the Russian I-O tables had a serious drawback, shown by marked magnitudes of imbalances between demand (row sums) and supply (column sums) for various production sectors while it was useful to investigate the poor quality of data reported by enterprises and the tax evasion problems. Goskomstat made tremendous efforts to improve the first version of the IOT and finalized the well-balancing 100-sector IOTs and SUT (supply and use tables) at the beginning of 1999, while only aggregated 22-sector symmetric IOT was made public in 2000.

The benchmark 1995 IOTs/SUT were followed by annual aggregated IOTs/SUTs for 1996-2003 with 22 to 24 production sectors. They were compiled by Goskomstat or Rossian Statistical Agency or Rosstat because Goskomstat was reorganized as the Russian Statistical Agency in 1999 and now as the Federal State Statistics Service (Rosstat).

All Russian SNA IOTs for 1991-2003 had a serious drawback in the sector classification which simply amended non-material service sectors by maintaining traditional material sector classification (CINE; OKONKH). In 2004 Rosstat began to reorganize all SNA data, including IOT, based on the international standard classification of economic activites, namely NACE rev.1. Rosstat finalized 2004 IOTs or SUT (supply and use tables) based on NACE rev.1. A 15-sector version of 2004 SUT was made public in 2007 although due to the lack of information of intermediate transactions they are still on the half way of completion.

2. Evolution of IOT in the USSR and the New Russia

2.1 Sector Classification

The Russian IOT during the Soviet era was based on the traditional material sectors. As is shown by Table 1, the 1987 IOT had 111 product sectors (economic activities) and its aggregated version had 18 product sectors.

In the MPS the concept of industry is quite different from the usage in the West in the sense that the Soviet industry includes mining and fishery as well as manufacturing. This terminology just recently disappeared in the Russian practice, while in China it is still employed as a key concept. Under the MPS the transport and communication services consist of only freight transport and communications related

Table 1 MPS IOT Sector Classification

Sources: Goskomstat, Russian 1987 IOTs with 111 sectors and 18 sectors.

Notes:

- 1. Industry includes mining and fishery as well as manufacturing.
- 2. In the oil and gas sector mining and manufacturing are mixed.
- 3. In the ferrous metallurgy sector mining and manufacturing are mixed.
- 4. In the ferrous metallurgy sector mining and manufacturing are mixed.
- 5. In the MBMW sector metal-block and machinery are mixed.
- 6. Aircraft and millitary MBMW may be included into the other machine industry.
- 7. Agricultural products are included into the light industry.
- 8. Fishery (primary industry) and manufacturing are mixed
- 9. Industry n.e.c. (not elsewhere classified) consists of extraction of asbestors, graphite, asphalt, mica, and abrasives; toys (except rubber); industrial diamonds, clays for oil refining; plastic machine parts; printing and bookbinding; musical instruments; wallpaper; cardboard containers; pencils, pens, ink, notebooks, general office supplies; jewelry; buttons; art products; commercial; laundering and dry cleaning; movie film and consumer film processing; water supply systems; processed animal feeds.
- 10. Agriculture (primary industry) excludes agricultural services.
- 11. Transport excludes passenger transport.
- 12. Communications exclude services for household.
- 13. Foreign trade is excluded.
- 14. The procurement is part of wholesale trade.
- 15. The technical supply is part of wholesale trade.
- 16. The other material production consists of collection of metal scrap; motion picture production; publishing; noncommercial hunting, fishing, and trapping; gathering of wild fruits, nuts, herbs, and so on.

to production through the exclusion of the passenger transport and individual communication services. This method was rejected just after the introduction of SNA.

The very specific feature of the Soviet IOT practice can be found in the treatment of the trade sector excluding foreign trade services and revenues. The Soviet national income implicitly included the foreign trade revenues generated by the differences between foreign and domestic prices of exports and imports. However, the foreign trade revenues were completely omitted in the Soviet IOT. This peculiarity disappeared with the collapse of the USSR.

Another specific feature of the Soviet IOT practice is the treatment of all aircrafts and some military machinery goods which are incorporated into the "other machine industry" sector. This "other machine industry" corresponds to the government industry in the U.S. practice, while aircraft industry is clearly shown in the US IOT. Surprisingly, this Soviet feature still remains in the present Russia.

Access to the Soviet and Russian IOTs has also been very limited. The publication of the Soviet and Russian IOTs for 1959-1972 was very strange because only part of these IOTs (the first quadrant with some omissions) was made public. During the Soviet era none of IOTs for 1977-1987 was made public. Present Russian IOTs have been published. To our regret, however, only aggregated IOTs have been so far available.

As was stated, the SNA sector classification in the early transition stage (CINE; Nation-wide Russian Classification of Industries of the National Economy; in Russian acronym OKONKH) was very insufficient. As Table 2 shows, the SNA 22-secor classification was constituted through the addition of non-material services (sectors 19-22) and the redefinition of material service sectors (transport and communications, and trade) in the MPS classification. The SNA 24-sector classification was obtained only by disaggregating the oil and gas sector of the 22-sector code into 3 sub-sectors. This disaggregation, which responded to our requirement, was rather important in the analysis of the peculiarity of the Russian economy, namely the enlargement of the trade sector. However, it did not show any progress in the principle of the sector classification.

The new Russian classification, RCEA (Russian Classification of Economic Activities; in Russian acronym OKVED) was introduced in compiling the 2004 IOT or SUT. This is totally in line with EACE rev.1 (nomenclature générale des activités économiques dans les Communautés Européennes; statistical classification of economic activities in the European Community) corresponding to ISIC rev.3. In another word RCEA is the Russian counterpart of EACE rev.1 and ISIC rev.3. As is

known, the first level (17 aggregated sectors; A-Q) of ISIC rev.3 would be taken over unchanged in NACE rev. 1. As is shown by Table 3, in the Russian IOT for 2004 and the SNA for 2002-2007 the first 15 sectors (A-O) of this first level are taken from NACE rev.1. Namely, two sectors (P. private households with employed persons; Q. extra-territorial organizations and bodies) of NACE rev.1 are omitted in RCEA. Table 3 displays the correspondence between 2004 and 2000-2003 IOTs with explanatory notes. As can be seen, the correspondence is one to many in most cases. This suggests that the conversion from the old code into the new code can not be a simple exercise for Rosstat.

It should be noted that only aggregated IOTs/SUTs have been published. Original IOTs/SUTs have been compiled at disaggregated levels with more than 100 production sectors.

The 1995 IOT system was first compiled at the 222-sector level by Goskomstat. Most sectors, namely 207 of 222, were rather traditional: the 187-industry (mining and manufacturing) sectors, the 2-construction sectors, the 3-agriculture sectors, the 3-forestry sectors, the 1-transportation, the 1-communications sector, the 3-trade sectors, the 2-technical supply sectors, the 1-information services sector, and the 4-'other material production' sectors. Newly introduced sectors were the followings: the real estate, the market research, the mineral resource research, the 4-housing and utilities sectors, the health and social security, the education, the culture and arts, the sciences, the finance and credits, the insurance and pension, the administration, and the non-profit organization body services. Its final version was prepared at the 100-sector aggregated level, and the 22-sector version was officially published.

Notes: Author's compilation based on Ustinova (2007), NACE rev.1 and OKONKH.

Following the benchmark IOT annual IOTs were compiled at the 100-sector level although only aggregated IOTs with 22 to 24 sectors were published.

Rosstat also first attempted to compile the 2004 IOT/SUT system at the 165/155-sector and 355-product level. Rosstat prepared its latest version at the 60-sector aggregated level, and published the 15-sector version.

2.2 Prices employed

The Soviet IOTs were constructed at purchasers' prices with double accounting of distribution margins. Each element, including exports and imports, therein was

evaluated at uniform domestic prices. This led to the exclusion of foreign trade revenues in the IOTs. We assume that all supplementary tables of trade and transport margins, net taxes on products and imports must have been compiled. Exports and imports were measured at FOB and CIF respectively.

Russian IOTs and SUTs for 1991-2004 have been compiled at both basic and purchasers' prices. Exports and imports have been evaluated at actual foreign trade prices. Foreign trade activities and revenues have been recorded on the trade sector. All supplementary tables of trade and transport margins, net taxes on products and imports have been compiled. Exports and imports have been measured at FOB and CIF respectively.

2.3 Consistency with SNA

After the break-up of the USSR the Russian statistics authority made efforts to re-establish the national accounts based on SNA 1993 and its recommendations. We can state that their efforts for these fifteen years result in a good consistency with SNA although they still suffer from the statistical difficulties, including a large amount of the non-observed economy (20 to 22% of GDP) and the lack of periodical renovation of economic census and benchmark IOT.

3. The Most Recent IOT of Russia

As for Russia we should note the followings:

- (1) The most recent benchmark IOT of Russia is still the 1995 IOT.
- (2) The most updated IOT based on the old classification (CINE) is 2003 IOT as the final version with a high perfection level.
- (3) The most recent IOT based on the new classification of economic activities (RCEA; EACE rev.1; ISIC rev.3) is 2004 IOT/SUT as a preliminary version with a low perfection level.

3.1 The 1995 Benchmark IOT

This system originally consisted of the following eight tables: (1) a supply (resource) table (the transpose of a make table in SNA 1968); (unpublished) (2) a use table; (unpublished) (3) a symmetric product-by-product IOT at purchasers' prices; (4) a symmetric product-by-product IOT at basic prices; (5) an import table (matrix); (6) a transport margin table (matrix); (7) a trade margin table (matrix); and (8) a table (matrix) of net taxes on products.

Table 4 shows the supply table consolidated into ten sectors (unpublished). As can be seen, this table almost entirely conforms to a supply table as recommended by SNA 1993 (UN et al., 1993, Table 15.1S) except for the sector classification code.

Notes: Figures with (*) and (**) denote the amounts subtracting corresponding margins.

As was noted, "industry" in the Soviet and Russian IOT terminology included both mining and manufacturing until 2006. By reading the first ten columns along each row, one can see the products and services in any given sector were supplied by a number of different sectors. It should be noted that the main part of the supply table, which consists of the elements in the first ten rows and first ten columns, was displayed at basic prices which are obtained by subtracting distribution margins and net taxes on products from purchasers' prices. The term "basic prices" is not much used in Japan and the United States, but it is widely used in European countries which impose high value added taxes, and it is one of the basic concepts employed in SNA 1993. Basic prices are also obtained by subtracting the net taxes on products from the producers' prices.

Column 11 of Table 1 totals sectoral own final outputs (uses) by households. Its content also accorded with SNA 1993 and its magnitudes featured a transitional character of the Russian economy. The sum of outputs by households accounted for 9% of the total output at basic prices. The agricultural output by households showed a marked value, 46%, of the total output by the agriculture sector. According to other Goskomstat sources, the agricultural value added by household showed 69% of the total value added by the agricultural sector in 1995. The trade output by households also showed a rather high value, 23% of the total trade sector output. The estimate of output by households enabled us to capture one of the main activities in the informal economy of Russia and to derive a rather reasonable estimate of the Russia's GDP.

Adding Column 12, imports, to Column 11 gives us the total supply at basic prices seen in Column 14. In Columns 15 through 22, distribution margins, import duties, taxes on products and subsidies on products (deduction) were added to the total supply at basic prices so as to obtain the total supply at purchasers' prices calculated in Column 23.

The row 11 "direct purchases abroad by residents", also based upon SNA 1993, was a category which could not be ignored for the Russia in transition because individually operated shops relying on goods imported by individuals (the so called "shuttle trade") played an important role to satisfy demand for imported goods. Indeed, the direct purchases abroad by residents amounted for more than 14% of the total import. Further, this table, for the first time, clealy showed import duties, all categories of taxes and subsidies on products, and distribution margins for all sectors. They were not displayed in the annual national income statistics by Goskomstat.

Table 5 is the symmetric 1995 product-by-product IOT at purchasers' prices, aggregated into the ten production sectors. Elements of the first quadrant in this table, shown at purchasers' prices, seem to be the same as those in IOT compiled so far. However, it should be noted that the sectoral total outputs in the table were shown at basic prices. This was different from the formulas employed so far. The advantage of employing this method was that it resolved the previous problem, namely the so

called "double accounting" problem of distribution margins, in the Soviet/Russian IOT at purchasers' prices. Formally, the form used for Japan's I-O tables at purchasers' prices was adopted.

The organization of Row 11, "direct purchases abroad by residents," and Row 12, "direct purchases in domestic markets by non-residents," accorded with the recommendations made in SNA 1993.

Further, Column 17, "net acquisition of valuables," was also based on SNA 1993. This column is very important for Russia with its vast natural resources.

The appearance of the concept "mixed income" in the value added quadrant also derived from SNA 1993. This concept covered a part of informal incomes in Russia. The gross mixed income in Table 5 amounted to 12.4% of GDP.

FISIM in Row 19 and Column 11 showed the total sum of "financial intermediation services indirectly measured" in SNA 1993 which was added to the intermediate input of the finance sector and subtracted from the total value added. The sector-specific distribution of this total was not calculated in the original Russian IOTs.

In the Soviet IOT all the activities of construction sector were defined as the investment demand while Table 5 shows that intermediate demand existed in the construction sector. This accounted for over 10% of the sector's investment demand in Table 5.

Table 6 shows the aggregated product-by-product IOT at basic prices where all the elements of the intermediate transaction quadrant and final demand quadrant as well as the sectoral output totals were shown at basic prices. The IOT at producers' prices can also be prepared through distribution margin and net tax matrixes. Tables 5 and 6 show a competitive type IOT. Non-competitive IOT can easily be compiled through the import matrix.

Table 7 shows a symmetric product-by-product 22-sector IOT at producers' prices, compiled by the author based on Table 6 and distribution margin and net tax matrixes. This table needs two adjustments for the standard input-output analysis of the Russian economy. First, the FISIM can be distributed among sectors in proportion to sectoral intermediate input share in the total intermediate input. Second, the sectoral distribution ratios of the direct imports abroad by residents, which Goskomstat estimated for 1993, can be employed for 1995: 40% for the machine-building and metal-working sector; 30% for the light industry; 8% for the food industry, 6% for the industry n.e.c. (not elsewhere classified), 7% for the transportation and communications, 5% for the education, health, culture and arts, 2% for the housing and public utilities, 2% for the finance, credit, insurance and administration. The direct purchases in Russia by non-residents, which mainly consist of souvenirs of Russia purchased by tourists, can be omitted from the table.

As is well known, IOTs provide a database for checking the consistency of statistics in flows of goods and services derived from different sources. The input-output system is also appropriate for computing much of the economic statistics contained in the national accounts and detecting flaws. In compiling the new IOT, numerical consistency of IOT with other data including national income statistics was checked, and a number of sectoral indicators of output and intermediate consumption were revised (Masakova, 1999). Using a commodity flow method, the additional hidden outputs in the oil industry, the non-ferrous metals, the food industry, and the pipe-line transportation were found. On the other hand, the output of the science sector was reduced by 30% because in fact the scientific institutions made profits not from their own activities, but from activities of renting and leasing. The value added of the informal trade was also revised based on the I-O data on intermediate consumption. The total output of the agriculture sector was reduced in relation with the methodological change in measurement of live-stock. Intermediate consumption in the household sector for informal production of goods and services was also revised.

One of the remaining problems inherent to Russian IOT for the benchmark 1995 IOT was how to measure the output and value added (GDP) of the oil and gas sector. The major part of revenues of the oil and gas industry was generated from it's foreign trade activities. This was recorded not in the oil and gas sector but in the trade sector. The supply table, however, did not show two activities/products of the oil and gas sector (the oil and natural gas production and the trade production). Taxes on the oil and gas products were paid not by the oil and gas sector but by the trade sector (IOT), while they were added to the oil and gas sector (IOT) at producers' prices. These inconsistencies should be resolved if each sectoral value added of IOT is shown not at basic prices but at producers' prices or market prices.

Table 7 Russian 1995 Input-Output Table at Producers' Prices (thousands of rubles denominated on January 1, 1999).

3.2 The 2003 IOT/SUT based on the Old Classification

The benchmark 1995 IOT was followed by annual aggregated IOTs for 1996-2003. The last annual IOT system is the 2003 IOT/SUT (see appendix). How large is the oil and gas sector? This problem in 2003 can be shown by Table 8. When the value added data at basic prices is employed, Table 8 shows that the share of the oil and gas industry value added in the total value added accounts for only 8%. This is quite strange in comparison of data on exports of the oil and gas product. To resolve this problem, value added of the trade related to the oil and gas should be computed and this part of value added should be transferred to the oil and gas industry. Adding the transferred value added and the net taxes on the oil and gas product to the original value added of the industry (left-hand side column of Table 8) would yield the right-hand side column of Table 8. Namely, the GDP share of the oil and gas industry in 2003 amounts to 20% which sounds quite plausible. This change would lead to some modifications of annual IOT/SUT where some part of intermediate inputs and

value added of the trade sector in the original IOT/SUT should also be transferred to the oil and gas industry.

3.3 The 2004 IOT/SUT based on the New Classification

The published version of the 2004 IOT system (RCEA; EACE rev.1) consists of only supply and use tables (SUT). Rosstat did not provide the symmetric 2004 IOT as was done for 1995-2003.

Tables 9 and 10 display the supply table and use table for 2004. Imbalances between demands and supplies given by two tables are shown in the use table. These statistical discrepancies lie in the very small range.

Rosstat did not meet any difficulty in compiling the supply table at basic prices. When they found some lacks in the data of distribution margins and net taxes on products of a similar product group, they employed the available margin (net tax)-supply ratios of a product in the 1995 benchmark IOT at basic prices in estimating the non-available data.

Rosstat did not face any problem in estimating all items of final demand and sectoral totals of intermediate demand for fully disaggregated 355 products. Household final consumption by product was estimated by using the household budget survey data. Gross fixed capital formation for machinery and equipments by sector was estimated through the commodity flow method.

Rosstat met serious difficulties in estimating the intermediate transaction matrix. Statistical reports from enterprises covered only 20% of all inputs. The commodity flow method and experts estimates based on the 1995 benchmark IOT were employed to estimate missing data on intermediate inputs. Surprisingly, Rosstat also made use of information through the internet sites of selected large scale enterprises.

Though only highly aggregated 2004 SUT at a preliminary stage were made public, we should not make light of the significance of the 2004 SUT based on the international standard classification of economic activities. These tables would provide the better database for a comparative analysis of input-output relations of Russian and European economies.

Let us here look at Table 11 which shows the Russian industrial structure of GDP in 2004 derived from the SUT and supplementary matrixes. The GDP share of the mining and quarrying sector including the oil and gas extraction was 12% while that of the trade was 18%. The GDP share of the oil and gas industry corresponding to Table 8 is estimated as about 20% in 2004-2006 by the Russian federal government. However, any accurate estimation of this figure has not yet been done.

4. Concluding Remarks

We reviewed the Soviet and Russian experiences of IOT for 80 years. Russian statistical authority made tremendous efforts to develop and improve IOT database at each stage. Although we respect these efforts, the published result was only 15-sector preliminary version. The 1995 benchmark IOT has been already obsolete. However, the Russian government with much budget surplus still hesitates to assign the budgetary funds for the new economic census and benchmark IOT which are essential in improving the quality and coverage of the present whole system of economic statistics. We hope that Rosstat will finalize their discussion with the ministry of finance about the new organization of economic census and benchmark IOT. There is no other way for further developments in Russian IOT and economic statistics in general.
